

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

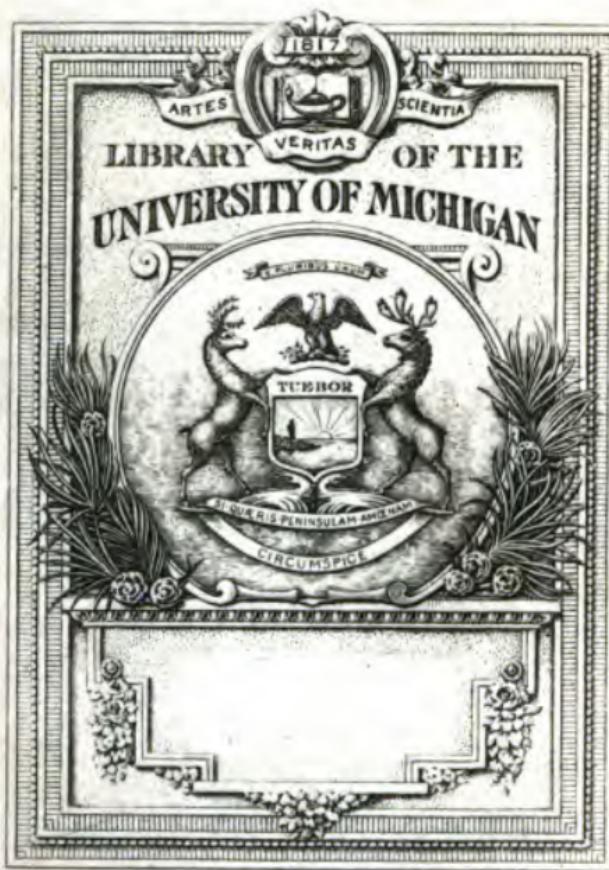

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

THE
MATHEMATICAL REPOSITORY.

ARTICLE I.

An Investigation of Theorems relating to the sums of the Powers of perpendiculars to all the sides of a regular polygon, from any point in the circumference of its inscribed circle.

By Mr. JAMES CUNLIFFE, Bolton-le-Moors.

ARTICLE 1. LEMMA. To find the sums of the various powers of the roots of the equation

$$v^n - Pv^{n-1} + Qv^{n-2} - Rv^{n-3} + S v^{n-4} \text{ &c.} = 0; \text{ } n \text{ being a whole number.}$$

Let the roots of the equation be denoted by $a, b, c, d \text{ &c.}$ the number of which is $n,$ as is very well known: Then by the property of equations

$$v^n - Pv^{n-1} + Qv^{n-2} - Rv^{n-3} + S v^{n-4} \text{ &c.} = (v - a)(v - b)(v - c)(v - d) \text{ &c. to } n \text{ factors.}$$

By taking the fluxions of the hyperbolic logarithms of each side of the equation, and dividing by v there will be had

$$\frac{nv^{n-1} - (n-1)Pv^{n-2} + (n-2)Qv^{n-3} - (n-3)Rv^{n-4} + (n-4)Sv^{n-5} \text{ &c.}}{v^n - Pv^{n-1} + Qv^{n-2} - Rv^{n-3} + S v^{n-4} \text{ &c.}}$$

$$= \left\{ \frac{1}{v-a} + \frac{1}{v-b} + \frac{1}{v-c} + \frac{1}{v-d} \text{ &c.} \right\} = \left\{ \begin{array}{l} \frac{1}{v} + \frac{a}{v^2} + \frac{a^2}{v^3} + \frac{a^3}{v^4} + \frac{a^4}{v^5} \text{ &c.} \\ \frac{1}{v} + \frac{b}{v^2} + \frac{b^2}{v^3} + \frac{b^3}{v^4} + \frac{b^4}{v^5} \text{ &c.} \\ \frac{1}{v} + \frac{c}{v^2} + \frac{c^2}{v^3} + \frac{c^3}{v^4} + \frac{c^4}{v^5} \text{ &c.} \\ \frac{1}{v} + \frac{d}{v^2} + \frac{d^2}{v^3} + \frac{d^3}{v^4} + \frac{d^4}{v^5} \text{ &c.} \end{array} \right.$$

by actually expanding the fractions $\frac{1}{v-a}$, $\frac{1}{v-b}$ &c. where it

is evident that the vertical columns must be continued to n terms.

Put $A = a + b + c + d$ &c. to n terms

$B = a^2 + b^2 + c^2 + d^2$ &c. to n terms

$C = a^3 + b^3 + c^3 + d^3$ &c. to n terms

$D = a^4 + b^4 + c^4 + d^4$ &c. to n terms. Then will

$$\frac{nv^{n-1} - (n-1)Pv^{n-2} + (n-2)Qv^{n-3} - (n-3)Rv^{n-4} + (n-4)Sv^{n-5} \text{ &c.}}{v^n - Pv^{n-1} + Qv^{n-2} - Rv^{n-3} + Sv^{n-4} \text{ &c.}}$$

$$= \frac{n}{v} + \frac{A}{v^2} + \frac{B}{v^3} + \frac{C}{v^4} + \frac{D}{v^5} \text{ &c. and by multiplying by}$$

$$v^n - Pv^{n-1} + Qv^{n-2} - Rv^{n-3} + Sv^{n-4} \text{ &c. there will be had}$$

$$nv^{n-1} - (n-1)Pv^{n-2} + (n-2)Qv^{n-3} - (n-3)Rv^{n-4} + (n-4)Sv^{n-5} \text{ &c.}$$

$$= nv^{n-1} + Av^{n-2} + Bv^{n-3} + Cv^{n-4} + Dv^{n-5} \text{ &c.}$$

$$- n Pv^{n-2} - PAv^{n-3} - PBv^{n-4} - PCv^{n-5} \text{ &c.}$$

$$+ n Qv^{n-3} + QA v^{n-4} + QB v^{n-5} \text{ &c.}$$

$$- n Rv^{n-4} - RA v^{n-5} \text{ &c.}$$

$$+ n Sv^{n-5} \text{ &c.}$$

Equating the co-efficients of the homologous terms, there will be had, $-(n-1)P = A - nP$; $(n-2)Q = B - PA + nQ$; $-(n-3)R = C - PB + QA - nR$; $(n-4)S = D - PC + QB - RA + nS$, &c. From the first of these equations $A = P$; from the second $B = PA - 2Q = P^2 - 2Q$; from the third $C = PB - QA + 3R = P^3 - 3PQ + 3R$; and from the fourth $D = PC - QB + RA - 4S = P^4 - 4P^2Q + 2Q^2 + 4PR - 4S$, &c. &c.

It

It may be remarked, by the way, from what is just deduced, that if, in any equation, the indices of the unknown quantity are whole numbers, and the co-efficients of the several terms rational; then the sums of the various powers of the roots will be rational also. The truth of this remark is evident from barely inspecting the formulæ themselves; for nothing is to be found in the formulæ but rational quantities. Therefore, if imaginary, or surd quantities are any ways concerned in the roots themselves, the affirmative and negative parts of such imaginary or surd quantities, which are concerned in the sums of the various powers of the roots must mutually destroy each other.

Art. 2. If v be the versed sine of a circular arc A , whose radius is r ; and V the versed sine of any multiple n of that arc or of nA ; then per Cor. 2, Prop. 29, Book I. of Emerson's Trigonometry,

$$\frac{(2v)^n}{2r^{n-1}} - \frac{enrA}{2v} - \frac{(2n-3)rB}{2 \cdot 2v} - \frac{(2n-4)(2n-5)rC}{3(2n-3) \cdot 2v} - \frac{(2n-5)(2n-7)rD}{4(2n-4) \cdot 2v}$$

&c. $\equiv \pm V$; where A, B, C, D &c. denote the preceding terms with their sines: therefore by restoring the values of A, B, C, D ,

&c. and multiplying the resulting expression by $\frac{r^{n-1}}{2^{n-1}}$ it becomes

$$\left. \begin{aligned} v^n - nr v^{n-1} + \frac{n(2n-3)r^2 v^{n-2}}{2^2} - \frac{n(2n-4)(2n-5)r^3 v^{n-3}}{2^3 \cdot 3} \\ + \frac{n(2n-5)(2n-6)(2n-7)r^4 v^{n-4}}{2^4 \cdot 3 \cdot 4} \text{ &c.} \end{aligned} \right\} \equiv$$

$$\frac{r^{n-1}}{2^{n-1}} \times \pm V.$$

The former of the preceding equations will also express the versed sine of the arcs $C + nA, 2C + nA, 3C + nA, 4C + nA$ &c. where C denotes the whole periphery of the circle. Therefore the several values of v , or roots of the preceding equation

will be the versed sines of the arcs, $A, \frac{C}{n} + A, \frac{2C}{n} + A, \frac{3C}{n} + A, \frac{4C}{n} + A$ &c. continued to n terms.

Art. 3. Fig. 496, pl. 27. If a regular polygon the number of whose sides is n , be circumscribed about a circle; M', M'', B_2

M'' ,

M'', \dots, M'' being the points of contact with the sides; and if from any point P , in the arc $M'M''$ perpendiculars PQ , PR , PS , &c. be drawn to the sides M' , M'' , M''' &c. these \perp s will be respectively equal to the versed sines of the arcs PM' , PM'' , PM''' &c.

Demonstration. Through the point of contact M' , draw the diameter $M'N$ and Pn perpendicular to it. Then $QM'n$ is a right angle (Eu. 18. III.), wherefore the figure $QM'nP$ is a rectangle, and (Eu. 34. I.), $PQ = M'n$, the versed sine of the arc PM' . And in the same manner it may be demonstrated that PR is equal to the versed sine of the arc PM'' &c.

Now if the diameter $M'N = 2r$, $C =$ the whole periphery of the circle, and arc $PM' = A$; then will $\frac{C}{n}$ be equal to each of the arcs $M''M'$, $M'M''$, $M''M'''$ &c. therefore $PM'' = \frac{C}{n} + A$, $PM''' = \frac{2C}{n} + A$, &c. and the perpendiculars PQ , PR , PS , &c. being respectively equal to the versed sines of the arcs A , $\frac{C}{n} + A$, $\frac{2C}{n} + A$ &c. will manifestly be the roots of the equation in Art. 2.

Art 4. It is required to find the sums of the various powers of the perpendiculars PQ , PR , PS , &c.

By comparing the co-efficients of the homologous terms of the equations in Article 1 and 2, there will be had $P = nr$; $Q = \frac{n(2n-3)r^2}{2}$; $R = \frac{n(2n-4)(2n-5)r^3}{2^3 \cdot 3}$; $S = \frac{n(2n-5)(2n-6)(2n-7)r^4}{2^4 \cdot 3 \cdot 4}$ &c.

Then $A = P = nr =$ to the sum of all the perpendiculars PQ , PR , PS , &c.

$B = PA - 2Q = nr^2 - \frac{n(2n-3)r^4}{2} = \frac{3nr^4}{2} =$ to the sum of the squares of all the perpendiculars PQ , PR , PS , &c.

$C = PB - QA + 3R = \frac{3nr^4}{2} - \frac{n^2(2n-3)r^6}{2^2} + \frac{n^2(2n-4)(2n-5)r^8}{2^3} = \frac{5nr^8}{2} =$ to the sum of the cubes of all the perpendiculars PQ , PR , PS , &c.

$D =$

$$\begin{aligned}
 D = PC - QB + RA - 4S &= \frac{5n^4r^4}{2} - \frac{3n^4(2n-3)r^4}{2^2} \\
 &+ \frac{n^4(2n-4)(2n-5)r^4}{2^3 \cdot 3} - \frac{n^4(2n-5)(2n-6)(2n-7)r^4}{2^4 \cdot 3} \\
 &= \frac{35nr^4}{8} = \text{to the sum of the fourth powers of all} \\
 &\text{the perpendiculars } PQ, PR, \text{ &c.}
 \end{aligned}$$

And by proceeding in the same way we shall obtain $\frac{63nr^5}{8}$ for the sum of the fifth powers of the said perpendiculars.

The two formulæ for the sum of the squares and sum of the cubes of the perpendiculars $PQ, PR, PS, \text{ &c.}$ agree perfectly with what is demonstrated by Messrs. Lowry and Swale in the first volume of the Repository.

ARTICLE II.

Improved Solutions to some Curious Mathematical Problems.

PROB. I. *By Mr. JAMES CUNLIFFE.*

TO find three square numbers, such, that the difference of every two of them may be a square number.

SOLUTION.

Let the numbers be denoted by $x^2, y^2, \text{ and } z^2;$ then by the question $x^2 - y^2 = a^2, x^2 - z^2 = b^2, \text{ and } y^2 - z^2 = \text{a square.}$ From the two first equations $x^2 = a^2 + y^2 = b^2 + z^2.$

Put $b = a + sv$, and $z = y = rv.$ Then $a^2 + y^2 = b^2 + z^2 = (a + sv)^2 + (y - rv)^2 = a^2 + y^2 + 2sav - 2ryv + s^2v^2 + r^2v^2;$ therefore,

$$\begin{aligned}
 v &= \frac{2ry - 2sa}{r^2 + s^2}, \text{ and } z = y - rv = y - \frac{2r^2y - 2rsa}{r^2 + s^2} = \\
 &\frac{2rsn - v(r^2 - s^2)}{r^2 + s^2}.
 \end{aligned}$$

But $x^2 = a^2 + y^2,$ theref. put $(r^2 + s^2)2mn = a,$ and $(r^2 + s^2)(m^2 - n^2) = y,$ then will

$x = (r^2 + s^2)(m^2 + n^2), \text{ and } z = 4rsmn - (r^2 - s^2)(m^2 - n^2).$ Wherefore

$y^2 - z^2 = (r^2 + s^2)(m^2 - n^2) - (r^2 - s^2)(m^2 - n^2) + 8rs(r^2 - s^2)mn$
 $(m^2 - n^2) - 16r^2s^2m^2n^2 =$
 $= 4r^2s^2(m^2 - n^2) + 8rs(r^2 - s^2)mn(m^2 - n^2) - 16r^2s^2m^2n^2 =$
 $\text{a square by the question. Assume } 2rs(m^2 + n^2) -$
 $2mn(r^2 - s^2) \text{ for its root, and then,}$
 $4r^2s^2(m^2 - n^2) + 8rs(r^2 - s^2)mn(m^2 - n^2) - 16r^2s^2m^2n^2 = [2rs(m^2 + n^2)$
 $- 2m(r^2 - s^2)]^2$
 $= 4r^2s^2(m^2 + n^2) - 8rs(r^2 - s^2)mn(m^2 + n^2) + (r^2 - s^2)^2 4m^2n^2, \text{ which}$
 $\text{being properly reduced gives } \frac{m}{n} = \frac{r^4 + 6r^2s^2 + s^4}{4rs(r^2 - s^2)}; \text{ whence it}$
 $\text{appears that } m \text{ and } n \text{ may be expounded by any two numbers in the}$
 $\text{ratio of } r^4 + 6r^2s^2 + s^4 \text{ to } 4rs(r^2 - s^2) \text{ respectively, where } r \text{ and } s$
 $\text{may be taken at pleasure.}$

For example, if $r = 3$ and $s = 1$, then $\frac{m}{n} = \frac{126}{96} = \frac{17}{12}$;

therefore put $m = 17$, and then $n = 12$, whence $x = 4330$,
 $y = 1450$, and $z = 1288$, which are the roots of three numbers
with the required property. Or their halves, viz. 2165, 725,
and 644 will be the roots of three squares that will answer.

Or the solution may be as follows.

Making use of the expressions for x , y , and z , which were obtained in the foregoing solution, it is plain that if we can determine $\frac{z+y}{2}$ and $\frac{z-y}{2}$, each equal to a rational square, the question will be answered, for then $\frac{z+y}{2} + \frac{z-y}{2} = \frac{z^2 - y^2}{4}$ must be a rational square, because each of its factors is so. Now $\frac{z+y}{2} = s^2(m^2 - n^2) + 2rsmn$, and $\frac{z-y}{2} = r^2(n^2 - m^2) + 2rsmn$ are both to be squares; let the first of them be divided by s^2 , and the other by r^2 , and the quotients will be $m^2 - n^2 + 2tmn$, and $n^2 - m^2 + \frac{2mn}{t}$, by putting $t = \frac{r}{s}$. Now these two last expressions must manifestly be still square numbers; therefore assume $qn - m$ for the root of the first of them, that is, put $m^2 - n^2 + 2tmn = (qn - m)^2 = q^2n^2 - 2qnm + m^2$, whence $n = 2m \times \frac{t+q}{q^2+1}$, which being written for n in the other expression there will be had

$$n^2 - m^2$$

$$n^2 - m^2 + (2nm \div t) = 4m^2(t+q)^2 \div (q^2+1)^2 - m^2 + 4m^2(t+q) \div t(q^2+1) =$$

$m^2 \div t^2(q^2+1)^2 \times [4t^2(t+q)^2 - t^2(q^2+1)^2 + 4t(t+q)(q^2+1)]$ = a square, and therefore,

$$4t^2(t+q)^2 - t^2(q^2+1)^2 + 4t(t+q)(q^2+1) = 4t^4 + 8t^3q + t^2(6q^2 - q^4 + 3) + 4tq(q^2+1)$$
 must be a square. Assume $2t^2 + 2tq$ for the root of this square, and then

$$4t^4 + 8t^3q + t^2(6q^2 - q^4 + 3) + 4tq(q^2+1) = (2t^2 + 2tq)^2 = 4t^4 + 8t^3q + 4t^2q^2, \text{ whence}$$

$$s = \frac{r}{s} = \frac{4q(q^2 + 1)}{q^4 - 2q^2 - 3} \text{ and by means of this value of } s,$$

$$n = 2m \times \frac{t+q}{q^2+1} = m \times \frac{2q(q^2+1)}{q^4 - 2q^2 - 3}, \text{ or } \frac{m}{n} = \frac{q^4 - 2q^2 - 3}{2q(q^2 + 1)}.$$

From these conclusions it appears that r and s may be expounded by any two numbers in the ratio of $4 : (q^2 + 1)$ to $q^4 - 2q^2 - 3$, and at the same time m and n must be taken in the ratio of $q^4 - 2q^2 - 3$ to $2q(q^2 + 1)$ respectively where q may be taken at pleasure.

Example 1. If $q = 2$, then $\frac{r}{s} = \frac{4q(q^2 + 1)}{q^4 - 2q^2 - 3} = \frac{40}{5} = 8$, and $\frac{m}{n} = \frac{q^4 - 2q^2 - 3}{2q(q^2 + 1)} = \frac{5}{20} = \frac{1}{4}$; wherefore we may

put $r = 8$, $s = 1$, $m = 1$, and $n = 4$; whence $x = (r^2 + s^2)(m^2 + n^2) = 65 \times 17 = 1105$, $y = (r^2 + s^2)(m^2 - n^2) = 65 \times 15 = 975$, and $z = 4rsmn - (r^2 - s^2)(m^2 - n^2) = 128 + 945 = 1073$ which are the roots of three squares that will answer, and differ materially from those found by the first method of solution.

Example 2. Suppose $q = 4$, then $\frac{r}{s} = \frac{16 \times 17}{221} = \frac{16}{13}$,

and $\frac{m}{n} = \frac{221}{8 \times 17} = \frac{13}{8}$, therefore we may take $r = 16$, $s = 13$, $m = 13$, and $n = 8$, then $x = 425 \times 233 = 99025$, $y = 425 \times 105 = 44625$, and $z = 86528 - 9135 = 77393$ being the roots of three other squares that will answer the question.

Example 3. If $q = 5$, then $\frac{r}{s} = \frac{20 \times 26}{572} = \frac{10}{11}$, and $\frac{m}{n} = \frac{572}{10 \times 26} = \frac{11}{5}$, therefore we may take $r = 10$, $s = 11$, $m = 11$, and $n = 5$. Hence $x = 221 \times 146 = 82266$, $y = 221 \times 96 = 91216$

24216, and $z = 24200 + 2106 = 26216$, which are also the roots of three squares that will answer; or taking their halves, viz. 16133, 10608, and 13108 they will be the roots of three squares that will answer.

A different value of t may be obtained as follows.

It has been shewn that $4t^4 + 8t^3q + t^2(6q^2 - q^4 + 3) + 4tq(q^2 + 1)$ must be a square; wherefore assume $2t^2 + 2tq - \frac{q^4 - 2q^2 + 3}{4}$ for its root, and then $4t^4 + 8t^3q + t^2(6q^2 - q^4 + 3) + 4tq(q^2 + 1) = (2t^2 + 2tq - \frac{q^4 - 2q^2 + 3}{4})^2 = 4t^4 + 8t^3q + t^2(6q^2 - q^4 + 3) - tq(q^4 - 2q^2 - 3) + \left(\frac{q^4 - 2q^2 + 3}{16}\right)^2$,

which being properly reduced gives $t = \frac{r}{s} = \frac{(q^4 - 2q^2 - 3)}{16q(q^2 + 1)^2}$ in which q may be taken at pleasure.

If $q = 1$, then $t = \frac{r}{s} = \frac{16}{16 \times 4} = \frac{1}{4}$; whence $n = 2m \times \frac{t+q}{q^2+1} = \frac{5m}{4}$, or $\frac{m}{n} = \frac{4}{5}$; hence it appears, that we may take $r = 1, s = 4, m = 4$, and $n = 5$; whence $x = (r^2 + s^2)(m^2 + n^2) = 17 \times 41 = 697$, $y = (r^2 + s^2)(m^2 - n^2) = 17 \times -9 = -153$, and $z = 4rsmn - (r^2 - s^2)(m^2 - n^2) = 320 - 135 = 185$, which are the roots of three squares that will answer, and are properly the roots of the least numbers that have the required property.

Or the solution may be as follows.

Let x^2, y^2 , and z^2 denote the required squares, then by the question $x^2 - y^2 = a^2$, and $x^2 - z^2 = b^2$, the difference of these two equations is $y^2 - z^2 = b^2 - a^2$, which must also be a square by the question: put $y = b - rv$, and $z = a - sv$, then

$$y^2 - z^2 = b^2 - a^2 = (b - rv)^2 - (a - sv)^2 = b^2 - a^2 - 2rbv + 2sav + r^2v^2 - s^2v^2, \text{ which gives}$$

$$v = \frac{2rb - 2sa}{r^2 - s^2}; \text{ whence } y = b - rv = \frac{2rsa - b(r^2 + s^2)}{r^2 - s^2}, \text{ & } z =$$

$$a - sv = \frac{a(r^2 + s^2) - 2rsb}{r^2 - s^2}$$

Now $y^2 - z^2 = b^2 - a^2$ must be a square number by the question, therefore put $(s^2 - r^2)(m^2 - n^2) = b$, and $(s^2 - r^2)2mn = a$, then,

$y = (r^2 + s^2)(m^2 + n^2) - 4rsmn$, and $z = 2rs(m^2 + n^2) - 2mn(r^2 + s^2)$; from whence and from the first equation,

$$\begin{aligned} x^2 &= a^2 + y^2 = (s^2 - r^2)^2 4m^2 n^2 + (r^2 + s^2)^2 (m^2 + n^2) - 8rs(r^2 + s^2)mn \\ &\quad (m^2 + n^2) + 16r^2 s^2 m^2 n^2 \\ &= (r^2 + s^2)^2 (m^2 + n^2) - 8rs(r^2 + s^2)mn(m^2 + n^2) + (r^2 + s^2)^2 4m^2 n^2 = \text{a square.} \end{aligned}$$

Assume $x = 4rsmn - (r^2 + s^2)(m^2 - n^2)$, then will $x^2 = (r^2 + s^2)^2 (m^2 + n^2)^2 - 8rs(r^2 + s^2)mn(m^2 + n^2) + (r^2 + s^2)^2 4m^2 n^2$ $= [4rsmn - (r^2 + s^2)(m^2 - n^2)]^2 = 16r^2 s^2 m^2 n^2 - 8rs(r^2 + s^2)mn(m^2 - n^2) + (r^2 + s^2)^2 (m^2 - n^2)^2$,

which by proper reduction gives $m = n \times \frac{2rs(r^2 + s^2)}{r^2 + s^2}$; put $n = r^2 + s^2$; then $m = 2rs(r^2 + s^2)$, where r and s may be taken at pleasure.

Example. If $r = 2$ and $s = 1$, then $n = r^2 + s^2 = 17$, and $m = 2rs(r^2 + s^2) = 20$; whence $x = 4rsmn - (r^2 + s^2)(m^2 - n^2) = 2165$, $y = (r^2 + s^2)(m^2 + n^2) - 4rsmn = 725$, and $z = 2rs(m^2 + n^2) - 2mn(r^2 + s^2) = -644$.

PROB. II. By Mr. JAMES CUNLIFFE.

To find three square numbers, such, that the sum of every two of them may be a square number.

SOLUTION:

Let x^2 , y^2 , and z^2 denote the three squares : - then by the question $x^2 + y^2 = a^2$, $x^2 + z^2 = b^2$, and $y^2 + z^2 = c^2$ a square ; from the two first of these equations $x^2 = a^2 - y^2 = b^2 - z^2$. It appears, therefore, from hence, that a , and y , must be so expressed, that the difference of their squares $a^2 - y^2$ may be a rational square, whose root is the value of x ; and moreover, b and z , must be determined in such a manner from thence, that $a^2 - y^2 = b^2 - z^2$.

From what is done in the last solution to the preceding question it is obvious that we may take $(s^2 - r^2)(m^2 + n^2) = a$, and $(s^2 - r^2)2mn = b$, whence $x = (s^2 - r^2)(m^2 - n^2)$; for then $z = 2rs(m^2 + n^2) - 2mn(r^2 + s^2)$. Wherefore

$$\begin{aligned} y^2 + z^2 &= (s^2 - r^2)^2 4m^2 n^2 + 4r^2 s^2 (m^2 + n^2)^2 - 8rs(r^2 + s^2)mn(m^2 + n^2) + (r^2 + s^2)^2 4m^2 n^2 = 4r^2 s^2 (m^2 + n^2)^2 - 8rs(r^2 + s^2)mn(m^2 + n^2) + (r^2 + s^2)^2 8m^2 n^2 = \text{a square by the question. Assume } 2rs(m^2 - n^2) + (r^2 + s^2)2mn \text{ for the root of this square ; then will} \\ &4r^2 s^2 (m^2 + n^2)^2 - 8rs(r^2 + s^2)mn(m^2 + n^2) + (r^2 + s^2)^2 8m^2 n^2 = \\ &[2rs(m^2 - n^2) + (r^2 + s^2)2mn]^2 = 4r^2 s^2 (m^2 - n^2)^2 + 8rs(r^2 + s^2)mn(m^2 - n^2) + (r^2 + s^2)^2 4m^2 n^2, \text{ which by reduction gives } n = m \times \end{aligned}$$

$\frac{4rs}{r^2 + s^2}$; put $m = r^2 + s^2$, and then $n = 4rs$, where r and s may be taken at pleasure.

Example.

Example. If $r = 1$ and $s = 2$, then $m = r^2 + s^2 = 5$, and $n = 4rs = 8$, whence $x = (s^2 - r^2)(m^2 - n^2) = 3 \times -39 = -117$, $y = (s^2 - r^2)2mn = 3 \times 80 = 240$, and $z = 2rs(m^2 + n^2) - (r^2 + s^2)2mn = 4 \times 89 - 5 \times 80 = -44$. Therefore 240, 117, and 44 are the roots of three squares the sum of every two of which will be a square, and are the least that have hitherto been found. The discovery of these numbers is attributed to EULER; but whoever was the first discoverer, they are obviously the first numbers that present themselves by the above method of solution.

(To be continued.)

ARTICLE III.

ON CONTINUED SURDS, &c.

By Mr. BENJ. GOMPERTZ.

I. If $x^2 - x = a$, x will be equal

$$\sqrt{a+x} = \sqrt{a + \sqrt{a+x}} = \sqrt{a + \sqrt{a + \sqrt{a+x}}} = \sqrt{a + \sqrt{a + \sqrt{a + \sqrt{a+x}}}}, \text{ ad infinitum.}$$

II. If $x = \sqrt[3]{a^2b}$, x^4 will be $= a^2bx$, and therefore,

$$x = \sqrt{a + \sqrt{bx}} = \sqrt{a \sqrt{b} \sqrt{a \sqrt{bx}}} = \sqrt{a \sqrt{b} \sqrt{a \sqrt{b}}}, \text{ ad infinitum.}$$

Which demonstrates John Bernoulli's Solutions, See Emerson's *Miscellanies*, page 433; these, Emerson affirms to be expressions of infinite value, and on that account that Bernoulli's Solutions are wrong. That they are not of infinite value is plain from above, as also from the solutions in the *Miscellanies*; and that the expressions are not even diverging may be thus generally demonstrated.

1. If a be equal or greater than unity, $\sqrt{a + \sqrt{a}}$ may be proved by the binomial theorem to be less than $\sqrt{a} + \frac{1}{2}$, therefore $\sqrt{a + \sqrt{a + \sqrt{a}}}$ is less than $\sqrt{a + \frac{1}{2} + \sqrt{a}}$, and therefore

therefore by all means less than $\sqrt{a + \frac{1}{2}} + \sqrt{a + \frac{1}{4}}$, or its equal $\sqrt{c + \sqrt{c}}$, (putting $c = a + \frac{1}{2}$), and still farther less than $\sqrt{c} + \frac{1}{2}$, therefore $\sqrt{a} + \sqrt{a + \sqrt{a + \sqrt{a + \sqrt{a}}}}$ is less than $\sqrt{a + \frac{1}{2}} + \sqrt{c}$, or its equal $\sqrt{c + \sqrt{c}}$, therefore far less than $\sqrt{c} + \frac{1}{2}$, and proceeding thus we continually find the same expression $\sqrt{c} + \frac{1}{2}$ to be greater than $\sqrt{a} + \sqrt{a + \sqrt{a + \sqrt{a + \text{&c.}}}}$ and so much the more so as we proceed.

Or thus whether a be greater or less than unity.

Put $b = a + 1$, therefore $\sqrt{a + \sqrt{a}}$ is less than $\sqrt{b + \sqrt{b}}$ and still less than $\sqrt{b} + \frac{1}{2}$, (b being greater than unity); therefore $\sqrt{a} + \sqrt{a + \sqrt{a}}$ is less than $\sqrt{a + \frac{1}{2} + \sqrt{b}}$ and still less than $\sqrt{b} + \sqrt{b}$ and still less than $\sqrt{b} + \frac{1}{2}$; therefore $\sqrt{a} + \sqrt{a + \sqrt{a + \sqrt{a}}}$ is less than $\sqrt{a + \frac{1}{2} + \sqrt{b}}$ and still less than $\sqrt{b} + \sqrt{b}$ and still less than $\sqrt{b} + \frac{1}{2}$, and thus we continually get the same expression $\sqrt{b} + \frac{1}{2}$ to be greater than $\sqrt{a} + \sqrt{a + \sqrt{a + \text{&c.}}}$ and the more so the further we proceed.

That the expression is greater than a needs no demonstration.

2. Here the expression may be written thus

$$a^{\frac{1}{2}} b^{\frac{1}{4}} a^{\frac{1}{8}} b^{\frac{1}{16}} a^{\frac{1}{32}} b^{\frac{1}{64}} \text{ &c.} =$$

$$a^{\frac{1}{2}} + \frac{1}{8} + \frac{1}{32} + \text{ &c.} \times b^{\frac{1}{4}} + \frac{1}{16} + \frac{1}{64} + \text{ &c.}$$

= (because the converging series $\frac{1}{2} + \frac{1}{8} + \frac{1}{32} + \text{ &c.} = \frac{2}{3}$ and the converging series $\frac{1}{4} + \frac{1}{16} + \frac{1}{64} + \text{ &c.} = \frac{1}{3}$) $a^{\frac{1}{2}} b^{\frac{1}{4}} = \sqrt[3]{a^2 b}$ the same as above, and it is here evident that the series converge.

$$\begin{aligned} \text{III. If } x^2 - 2ax = b, \text{ we have } x^4 - 2ax^2 = bx, \text{ and therefore} \\ x = \sqrt{+a\sqrt{bx+a^2}} = \sqrt{a} + \sqrt{a^2 + b\sqrt{a + \sqrt{bx+a^2}}} \\ = \sqrt{a} + \sqrt{a^2 + b\sqrt{a} + \sqrt{a^2 + b\sqrt{a + \sqrt{bx+a^2}}}} \end{aligned}$$

$$= \sqrt{a + \sqrt{a + b \sqrt{a + \sqrt{a + b \sqrt{a + \sqrt{a + \text{ad infinitum}}}}}}}$$

IV. Let $x^3 + ax = b$; therefore $x = \frac{1}{a}b + \frac{1}{a}x^3$

$$= \frac{1}{a}b \cdot \frac{1}{a} \times \left(\frac{1}{a}b - \frac{1}{a}x^3 \right)^3 = \frac{1}{a}b \cdot \frac{1}{a} \times \left\{ \frac{1}{a}b - \frac{1}{a} \times \left(\frac{1}{a}b - \frac{1}{a}x^3 \right)^3 \right\}^3$$

$$= \frac{1}{a}b \cdot \frac{1}{a} \times \left\{ \frac{1}{a}b - \frac{1}{a} \times \left[\frac{1}{a}b - \frac{1}{a} \times \left(\frac{1}{a}b, \text{ad infinitum} \right)^3 \right]^3 \right\}^3, \text{ and putting}$$

$$c = \frac{b}{a} \text{ it becomes } c - \frac{1}{a} \times \left\{ c - \frac{1}{a} \times \left[c - \frac{1}{a} \times \left(c, \text{ad infinitum} \right)^3 \right]^3 \right\}^3.$$

The computation by these series will be plain, by the following EXAMPLE. Let $x^3 - 10x = -3$, to find x . Compare this with the last theorem, and we have $a = -10$, $b = -3$, $c = -3$, $c^3 = -027$, $c - \frac{1}{a} \cdot c^3 = -3027$ nearly $= x$, or $c - \frac{1}{a} \cdot (c - \frac{1}{a} \cdot c^3)^3 = -3 + -002773 = -302773$, which differs from the true value of x but by 2 in the last place, and had we proceeded we might have had any degree of accuracy. Though what I have done here may not be of great importance, it may still be acceptable as it confirms Bernoulli's solutions.

ARTICLE IV.

*Answers to the Mathematical Questions proposed in
ARTICLE XLIV. Vol. II.*

I. QUESTION 211, answered by Mr. Gregory, of Cambridge.

WHEN it is required to determine the sun's altitude at 6 o'clock, and his amplitude at rising, from the latitude and declination given, the two following analogies are generally made use of :

1. As radius : sine latitude :: sine of sun's dec. : sine alt. at 6.
2. As cos. latitude : radius :: sine of sun's dec. : sine amplitude.

From the nature of which analogies it is manifest, that both the altitude at 6, and the amplitude will increase, as the latitude of the same name as the declination increases. And as neither the

altitude

altitude nor amplitude increases very fast or very irregularly, the former varying from 0° in lat. 0° , to about 15° in lat. 90° ; and the latter from $15^\circ 5' 24''$ (= the declination) in lat. 0° , to about 30° in lat. 60° , the method of Trial and Error, may here be adopted with sufficient accuracy and success.

Now, it is obvious upon slight consideration, that the latitude sought must be between 45° and 55° : suppose therefore, that the latitude is 50° ; then, applying the above analogies, we get $11^\circ. 30'. 13''$ for the altitude at 6, and $23^\circ. 53'. 30''$ for the amplitude: the sum of these and the declination is $50^\circ. 29'. 7''$ instead of 50° ; the error, therefore, is $29'. 7''$ or $1747''$ in excess. Again, suppose 52° the latitude; then, we obtain, $11^\circ. 50'. 17''$ for the altitude, and $25^\circ. 6'. 54''$ for the amplitude: the sum of these and the declination is $51^\circ. 56'. 35''$, instead of 52° ; hence the error arising from this assumption is $3'. 25''$ or $205''$ in defect. Whence by the common rule we find the north latitude = 51.78996 or $51^\circ. 47'. 24''$ nearly. The altitude at 6, corresponding to this latitude, and declination $15^\circ. 5'. 24''$ is $11^\circ. 48'. 13' \frac{1}{2}$, and the amplitude $24^\circ. 53'. 25' \frac{1}{2}$; the sum of these and the declination differ not more than $1'$ from the latitude; thus confirming the truth of the result. In this solution no notice has been taken of the change in the sun's declination, between the sun's rising and noon of the given day.

The same, answered by the Proposer, Mr. Croudace.

Put the sine and cosine of the declination = a and b , and the sine of the latitude = x . Then, by Spherics, the sine of the altitude at 6, is = ax , and the sine of the amplitude = $a \div \sqrt{1-x^2}$. But, by Emerson's Trigonometry, page 21, sine alt. \times cos. ampl. + cos. alt. \times sine ampl. is = to sine lat. \times cos. decl. — cos. lat. \times sine decl. that is,

$$ax \times \sqrt{\frac{c-x^2}{1-x^2}} + \sqrt{(1-a^2)x^2} \times \sqrt{\frac{a^2}{1-x^2}} = bx - a\sqrt{(1-x^2)}, \text{ by}$$

putting $c = 1 - a^2$. This equation reduced gives,

$$(bx \div a) \times \sqrt{(1-x^2)} - \sqrt{(c x^2 - x^2)} - \sqrt{(1-a^2 x^2)} + x^2 = 1.$$

Hence $x = .784429$ answering to $51^\circ. 40'. 5''$ north lat tide.

Answers were also received from Messrs. Barron, Bullock, Cunliffe, Davis, Lowry, May, Mertons Minor, and Thornaby.

II. QUESTION 219, answered by Miss Susan May.

It is evident that the objects A, B, C, D are in the circumference of a small circle of the sphere, whose diameter may be

VOL. III.

C

determined

determined from the distances given in the question. Now these distances are portions of a great circle of the sphere, and consequently the chords subtended by these distances may be found by reversing some of the rules in *Dr. Hutton's Mensuration*, and the diameter of the circle may be found by *Prob. 98, of Emerson's Algebra*.

But in the present case where the distances are so small, that the difference between the arcs and chords are inconsiderable, we shall avoid the trouble of calculating the lengths of the chords, by using the arcs in their stead.....Now, by the Prob. above-mentioned, we obtain 33.1784 for the diameter of the circle, and if O (fig. 497, pl. 27.) be the centre of the earth, GF the height of the hill, FE a tangent to the earth at E and EH be \perp to OF, we have, (by the sim. Δ s OFE, OEH,) $OE^2 = GH \times HF$: but OE is = 3978.87, and $EH = 16.5892 = \frac{1}{2}$, the diameter above found, therefore $OF = OE^2 \div OH = OE^2 \div \sqrt{(OE^2 - EH^2)} = 3978.904$; consequently $GF = .034$ miles = $.034 \times 5280 = 179.5$ feet nearly the height required.

The same, answered by Merones Minor.

Here are given the four sides of a trapezium inscribed in a circle to find the diameter, which, by *Simpson's Select Exercises*, *Prob. 35*, is = 33.1783 miles. Then $25000 : 33.1783 \div 2 : : 360 : 14.20$, the \angle at the centre of the earth subtended by the radius of the above circle; the natural secant thereof minus radius = .0000087 miles for the height of the hill to radius 1, which, $\times (25000 \times 5280) \div (2 \times 3.14159 \text{ &c.})$ gives 182.8 feet, the height required, by *Gardner's Logarithms*. Or by using *Hutton's Logarithms* the height = .0000085 miles (to radius 1) = 178.6 feet.

This question was also answered by Messrs. Barron, Buffham, Cunliffe, Davis, Gregory, Lowry, and Thornoby.

III. QUESTION 213, answered by Miss Susan May.

Fig. 498, Pl. 27. Let ACE, ADF be the segments, draw the diameter AQI and join AC. Then, by *Rule V. of Dr. Hutton's Mensuration*, $(2CB + \frac{4}{3}CA) \times \frac{4}{15}AB$ = the area of the segment ACE, and $.7854 \times AB^2$ is = the area of the greatest inscribed circle; therefore by the Question

$$(2CB + \frac{4}{3}CA) \times \frac{4}{15}AB : .7854 \times AB^2 :: 5 : 2, \text{ or}$$

$$CB + \frac{2}{3}CA : AB :: 1 : .407403, \text{ or}$$

$$CB + \frac{2}{3}CA : \sqrt{(CA^2 - CB^2)} :: 1 : .407403. \text{ But } (\text{Rule VI. ibid.})$$

$$CA - CB = \frac{1}{2} \times \text{Arc CAF} = 75, \text{ wherefore}$$

$$CA = \frac{75}{2} + \frac{1}{4}CB, \text{ and } CA^2 = \left(\frac{75}{2}\right)^2 + \frac{1}{4} \times CB + \frac{1}{16} \times CB^2. \text{ Then val } .$$

values being substituted in the above proportion it becomes

$$\frac{75}{6} + \frac{7}{6} \times CB : \sqrt{\left(\frac{75}{16} + \frac{150}{4} \times CB - \frac{15}{16} \times CB^2\right)} :: 1 : 407498.$$

Hence by means of a quadratic equation we obtain $CB = 18.8$ nearly, $CA = 23.45$, and $BA = 14.025$; consequently $AC^2 \div AB = AQ = 39.2$, the diameter of the least circle.

Again, by Rule *V. ibid.*

$$2AI \times \sqrt{\left\{3AB \div (3AI - AB)\right\}} = \text{the arc } DAF = 60, \text{ or}$$

$$4AI^2 \times 3AB \div (3AI - AB) = 60^\circ. \text{ Therefore}$$

$AI^2 = \left(\frac{60}{2}\right)^2 \times AI - 60 \times 5$; consequently $AI = 59.075$ the diameter of the greater circle. Wherefore $(AI^2 - AQ^2) \times .7854 = 1534$ square yards, the area included between the arcs of the circles, nearly.

The same, answered by Mr. Geo. Buffham, Boston.

Put $50 = l$, $.7854 = p$, $AC = y$, and $CB = x$. Then by the common rule for finding the length of an arc, $8y - 2x = 36$, or $y = \frac{1}{4}x + \frac{3}{8}l$; whence $AB = \sqrt{(.1^2 - x^2)} = \sqrt{(.1^2 l^2 - \frac{1}{16}x^2 + \frac{9}{64}l^2)}$, and the area of the circle $AGBK = p \times (.1^2 l^2 - \frac{1}{16}x^2 + \frac{9}{64}l^2)$. By Dr. Hutton's Menfuration, 4to edit. Rule IV. for finding the area of a circular segment, the area $CAE = (\frac{1}{16}x^2 + \frac{1}{3}l) \times \sqrt{.1^2 l^2 - \frac{1}{16}x^2 + \frac{9}{64}l^2}$. By the Question

$5:2 :: (\frac{1}{16}x + \frac{1}{3}l) \times \sqrt{(.1^2 l^2 - \frac{1}{16}x^2 + \frac{9}{64}l^2)} : p \times (.1^2 l^2 - \frac{1}{16}x^2 + \frac{9}{64}l^2)$; or $5p \times (.1^2 l^2 - \frac{1}{16}x^2 + \frac{9}{64}l^2) = (\frac{2}{15}x + \frac{2}{3}l) \times \sqrt{(.1^2 l^2 - \frac{1}{16}x^2 + \frac{9}{64}l^2)}$. This by reduction gives $x^2 - 3.89636x = 279.8783$, or $x = 18.79$. Hence the diameter of the less circle is $= 39.2$. And from the same rule the diameter of the greater circle is $= 59.0707$, and the difference required $= 1533^2$ square yards nearly.

Other solutions were received from Meffrs. Barron, Davis, Gregory, Hill, Lowry, and Swale.

IV. QUESTION 214, answered by Mr. John Barron, Spilby.

Fig. 499, Pl. 27. Put $D = AB = 6$ inches the diameter of the base, $b =$ the altitude $= 4$ inches, $m =$ a third part of the solidity $= 12.5664$, and $FB = x$. Then, $D:b :: x:bx \div D = DI$ the altitude of the part cut off. And by Rule *VI. Dr. Hutton's Menfuration*, the area of the part HRG is $= \frac{4}{3}x \times \sqrt{(Dx - \frac{3}{2}x^2)}$; therefore by Rule to Prob. 28, page 232, *ibid.*, we have

$$[\frac{4}{3}D \times \sqrt{(Dx - \frac{3}{2}x^2)} - \frac{4}{3}(D - x) \times \sqrt{(Dx - x^2)}] \times (bx \times D) = m. \quad \text{Hence}$$

Hence by the method of trial and error, x is found = 3.21 nearly for the first man's share. Again, by taking $m = \frac{2}{3}$ of the solidity = 25.1327, we find $x = 4.4$ nearly for the second man's share.

Messrs. Buffham, Davis, Gregory, Hill, Lowry, and May, also sent solutions to this question.

V. QUESTION 215, answered by Miss Susan May.

In Fig. 500, Pl. 27. Let C be the centre of the earth's shadow, O the centre of the moon at the first observation, A the centre at the middle of the eclipse, or when the obscuration is the greatest, I that at the beginning, and H that at the end. — About the centre C with the distance CO describe a circle $DOPB$ for the boundary of the earth's shadow, and let CAP be drawn, which will be \perp to HI , the relative path of the moon's centre. Join BC , BD , BO , PO , CO , CD , CH and CI . Then by the question, BD the distance between the illuminated cusps is given = 30'. 15", therefore its half, BE , is given = 15'. 7.5" = 907".5, and the semidiameter BO is given = 15'. 24" = 9.4"; therefore $OE = \sqrt{(PO^2 - BE^2)} = 173.83"$, and, by *Lamson's 43d Prop.* (vide *Repos. No. X.*) $OC = CP = BO \div 2OE = 2455".65$.

Again as, $6^{\circ} : 15'. 24" :: 1^{\circ} . 27'. 36" : 224'. 84 = AP$; therefore $AC = CP - AP = 2230".8$ and $AO = \sqrt{(OC^2 - AC^2)} = 1026".52$. Moreover $CI = CO + OB = 3379".65$,

and therefore $AI = \sqrt{(CI^2 - CA^2)} = 2535".89$. Now as

$29'. 45"$ (the horary motion) : 60' :: $\begin{cases} AI : 1h\ 25m.\ 14s. \\ AO : 0h.\ 34m.\ 30s. \end{cases}$ Hence $1h.\ 49m.\ 48s. + 34m.\ 30s. = 12h.\ 24m.\ 18s$, the middle, $12h.\ 24m.\ 18s. - 1h.\ 25m.\ 14s = 10h.\ 59m.\ 4s$, the beginning, and $12h.\ 24m.\ 18s. + 1h.\ 25m.\ 14s = 13h.\ 49m.\ 32s$, the ending.

The same, answered by Merones Minor.

The figure being drawn as before, bisect OD by the $\perp Ch$. Then in the $\triangle DEO$ we have DO , DE to find the $\angle DOE$ (COh) = $79^{\circ} . 9'. 35"$, and in the $\triangle COh$ we have all the \angle s and the side Oh to find $CO = 2455".64$. Then say as $6^{\circ} : 1^{\circ} . 27'. 36" :: 15'. 24" : 224".84$, and $2455".64 - 224".84 = 2230".8 = AC$; also $CO + DO = CI = 3379".64$. Now in the two right \angle d \triangle s CAO , CAI we have given CA , CO , CI to find $AO = 1026".5$, and $AI = 2235".9$, which, by the given horary motion of the moon from the sun will be passed over in

in $34'.$ $30''$. 25 and $1h.$ $25'.$ $14''$. 37 respectively. Hence by addition and subtraction,

the beginning was at $1h.$ $59m.$ $3'88s.$

the middle was at $1h.$ $24m.$ $18'25s.$

and ending was at $1h.$ $49m.$ $32'62s.$

* * In these solutions the moon's relative orbit has been considered as a straight line, and her motion therein as equable; since it was not the wish of the proposer to render the solution of the question more intricate by considering them otherwise.

Ingenious solutions to this question were received from Messrs. Davis, Gregory, Hill and Lowry.

VI. QUESTION 216, answered by Mr. John Andrew, of Cork.

CONSTRUCTION. Fig. 501, Pl. 27. With the given diameter DO describe a circle, and \perp thereto inscribe AB = the given base; join OB , to which add, by the 18, *V. of Simson's Geometry*, the line Bg , so that $Og \times gB$ may be = to the rectangle under DO and the given difference between the \perp and rad. of the inscribed circle. From O , to the circle, apply $OC = Og$; join AC , CB and ACB will be the Δ required.

DEMONSTRATION. Join DC , CO , and drop the \perp CP ; make $OQ = OB$, and draw $QG \parallel AB$. Now, it is well known, that Q is the centre and GP the radius of the circle inscribed in the ΔACB . Moreover by similar triangles

$OD : OC = Og : CQ = Bg : CG$, hence

$Og \times gB = OD \times CG$, and, by the construction,

$Og \times gB = OD \times$ the given difference;

therefore CG is equal to the given difference.

Q. E. D.

The same answered by Mr. James Cunliffe, of Bolton.

ANALYSIS. Let ACB be the required Δ inscribed in the given circle, DO a diameter of the circle bisecting the base AB in E ; join OB and OC .

Upon OC take $OQ = OB$, and Q is the centre of the inscribed circle, as is very well known. Draw $QG \parallel AB$ meeting the $\perp CP$ in G , and join DC . The Δ s ODC , and QCG are right angled and similar, therefore

$OD : OC = OB : CQ :: CQ : CG$; whence by Eu. 16. VI.

$CQ \times (CQ + OB) = OD \times CG$; now OD , OB and CG are all given, and CQ may be found by Prob. 18. Book V. *Simson's Geometry*, and from thence OC becomes known.

The same answered by Mr. W. Peacock, Birmingham.

In a circle, whose diameter is the given line DO, inscribe the chord AB, \perp to DO and equal to the given base. With the centre O and distance OA, or OB, describe the circle AIQB cutting DO at I. Make $OD : OF :: IF : \text{the given difference}$ (Eu. VI. 29. Playfair's Ed.), and from O, to the circle apply OC $\equiv OF$, and join AC, BC, so shall ACB be the Δ required.

For it is well known that the circle AIB is the *locus* of the centre of the inscribed circle, and if CP be drawn \perp , and QG \parallel to AB, we shall have by sim. Δ s, $OD : OC = OF : QC = FI : CG$; therefore it is manifest that CG is \equiv to the given difference.

The same, also by Mr. James Whalley, of Bolton.

ANALYSIS. Suppose DO the diameter of the given circle, AB, \perp to DO, the given base, and ACB the Δ required. Draw Cd \parallel to AB, then will dE represent the \perp in which take $dn =$ the given difference. Now (vide No. 3. of the Student) $Ex \times On = dn \times OE$, but dn and OE are both given, therefore (by Simpson's Geo. 18. V.) produce OE to π so that $On \times \pi E$ may be \equiv to the given rectangle $dn \times OF$, then will Ed be given, and all the other parts of the diameter will from thence be given, and the method of Construction evident enough.

Very neat answers to this question were also received from Messrs. Burdon, the proposer, Davis, Gregory, Hill, Lowry, and Swale.

VII. QUESTION 217, answered by the proposer, Mr. Bosworth.

The best method perhaps of answering Questions of this nature is, first, to find the centre of gravity of the lever, and then, supposing the whole matter it contains to be collected in that point, to find the common centre of gravity of the lever and the globe attached to it, which will be the place of the fulcrum. To apply this method in the present instance: the lever being equally thick and dense throughout, its centre of gravity is in the middle, that is, the length being 10 feet, at the distance of 5 feet from each end. A globe of lead, $4\frac{1}{2}$ inches diameter, weighs 17lbs, and as the weights of similar solids are in proportion to the cubes of their like dimensions we have $(4\frac{1}{2})^3 : 17 :: 6^3$, (the cube of the diam. of the given globe) : 47.8339lbs. weight of the given globe. Now, as the distance of the common centre of gravity of these bodies, and consequently of the fulcrum, from each end, is inversely as the weights, we have as 40 (weight of the lever) +

47.8339

47.8339 (weight of the globe) : 5 feet :: 40 : 2.27702515 feet.
distance of the fulcrum from the end at which the globe hangs.

The same, answered by Miss Susan May.

Fig. 502, Pl. 27. Let ADHE be a section of the lever, and let G be the point required. Take $FG = GH$, and draw $FB \parallel$ to HD . Then the equal parts $GCDH$, $GCBF$ on the different sides of the fulcrum G, will keep each other in equilibrio; therefore the weight suspended at H must be a counterpoise for the remaining part of the lever, that is for the part ABEF.

Let m be the centre of gravity of the part ABEF, then, by mechanics, the force of the part ABEF, to turn the lever about the fulcrum G, will be the same as a weight equal thereto placed at m ; consequently as the weight of the part ABEF is to the distance cd or GH , so is the weight of the lead to the distance mc .—Now since $am = mb$, and $bc = cd$, mc is $=$ half the length of the lever 5 feet, and the weight of the part ABEF is $= 8mb$, therefore, if w be $=$ to the weight of the lead ($= 46.326$ lbs.) we have $8mb : 5 - mb :: w : 5$, and, by reduction, $mb = 5w \div (40 + w) = 2.68321$, consequently $bc = 5 - mb = 2.31679$ the distance required.

The same, answered by Mr. John Barron, of Spilsby.

The weight of a leaden ball is $= \frac{2}{3}$ of the cube of its diameter, therefore $6^3 \times \frac{2}{3} = 48$ lbs. the weight of the given ball.

Let ad be $= 10$ the len. of the lever, $cd = x$, the distance from that end of the lever, from whence the ball is hung, to the fulcrum; then $10 - x = ac$ the other part of the lever. Since the weight of every foot of the lever is evidently $= 4$ lb., $4x$ will be the weight of the part GD , and $40 - 4x$ the weight of the part AG . The distance of the centre of gravity of the part DG from the point c is $= \frac{x}{2}$, and that of the part AG from the same point c is $\frac{10 - x}{2}$. Hence, by the nature of the question $\frac{x}{2} \times 4x + 48x = \frac{10 - x}{2} \times (40 - 4x)$. From this equation $x = \frac{200}{98} = 2.02027$ feet.

The same, answered by Mr. George Buffham.

Let ad represent the lever, w the globe of lead, the weight of which is found to be 46.326 lbs, and let c be the point where the

the fulcrum is to be placed. Put $cd = y$, then $ac = 10 - y$, the weights of which will be $4y$ and $40 - 4y$. By the property of the lever $(40 - 4y) \times (5 - \frac{1}{2}y) = 4y \times \frac{1}{2}y + 46.326y$; whence $y = 2.3168$ the distance from the end d to the point required.

The same, answered by Mr. David Davis.

Let F (fig. 503, pl. 27.) be the fulcrum on which the lever AB and weight W are supposed to rest in *equilibrio*: then, since the lever is equally thick throughout, if FC be equal to FA , the *momenta* of these two portions of the lever will be equal the one to the other, and we have to determine when the momentum of the part CB is equal to that of the weight W , both considered with respect to the fulcrum F . To perform this generally, put x for FB , y for AF or FC , s for 4 lbs, the weight of 1 foot in length of the lever, and w for the weight suspended from A : then yw will denote the momentum of W ; and CB being equal to $x - y$,

the distance FG of its centre of gravity from F being $y + \frac{x-y}{2}$

$$= \frac{x+y}{2}; \text{ we have } (x-y) \times s \times \frac{x+y}{2} = \frac{sx^2 - sy^2}{2}, \text{ for}$$

the momentum of CB . Hence this equation, $yw = \frac{sx^2 - sy^2}{2}$;

which reduced gives $x = \sqrt{y^2 + \frac{2wy}{s}}$. And from this general equation, any three of the four quantities x , y , w , or s , being given, the fourth may readily be found.

In the case before us, where $AB = 10$, we have $x = 10 - y$; which value of x equated with the foregoing, gives $10 - y =$

$$\sqrt{y^2 + \frac{2wy}{s}}; \text{ whence by proper reduction we soon obtain } y =$$

$$\frac{100s}{2as + sw} = \frac{200}{40 + w}, s \text{ being equal to 4.....Now, it is known,}$$

by repeated experiments, that a ball of lead of $4\frac{1}{2}$ inches diameter weighs 17 lbs; wherefore, we have, by the nature of similar solids, $(4\frac{1}{2})^3 : 6^3 :: 17 \text{ lbs} : 47.84391 \text{ lbs}$, the weight of the given globe, or the value of w ; which being substituted for it in the final equation above, gives $y = 2.277024898$ feet, $= AF$, the distance of the fulcrum from the end A .

This question was likewise very ingeniously answered by Messrs. Cunliffe, Gregory, Hill, Lowry, Marrat, Merones Minor, Peacock, and Swale.

VIII. QUESTION 218, *answered by Mr. Cunliffe.*

CONSTRUCTION. Fig. 504, Pl. 27. Make a right angled $\triangle BGO'$ such, that the leg BG shall be to the hypotenuse BO' in the given ratio of the base to the diameter of the circumscribing circle: at B take $BL \perp$ to BG and such that BG may be to BL in the given ratio of half the difference of the segments of the base to the perpendicular, and draw GL . Then with the centre O' and radius $O'B$ describe a circle cutting BG produced in A and the line GL in C ; join AC , BC , and the $\triangle ACB$ shall be similar to that required.

DEMONSTRATION. Upon AB drop the $\perp CP$; then because of the parallels PC , BL ; $GB : BL :: GP : PC$, the given ratio of half the difference of the segments of the base to the perpendicular, by the construction; and the rest is evident. Therefore the \triangle may be constructed either with the radius of the inscribed circle, or any other datum.

The same, answered by Merones Minor.

ANALYSIS. Suppose ACB the required \triangle , $DGI \perp$ to AB , the diameter of the circumscribing circle, and O the centre of the inscribed circle. Draw $CP \perp$ to AB and join CG . Then, the ratio of AB to DI being given, the vertical $\angle ACB$, is given; and OM , the radius of the inscribed circle, being given, CO is given. Hence this

CONSTRUCTION. Upon any assumed line di describe a circle and inscribe $ab \perp$ thereto, so that $ab : di = AB : DI$; take $ep : eg = GP : CP$, of any magnitude at pleasure; compleat the parallelogram ecg , and draw the diagonal ecC to cut the circle in C ; join Ca , Cb , Ci ; in Ci take CO of the given length, as found in the analysis, and describe the circle HMN , with the given radius of the inscribed circle; finally draw $AB \parallel ab$, to touch the circle HMN , and cutting Ca , Cb , in A and B ; so shall ACB be the \triangle required.

The same, answered by Mr. W. Peacock.

On any line DI as diameter describe a circle and apply $AB \perp$ to the diameter and of such a length that its ratio to DI may be the same as the given ratio of the base to the diameter. Let G be their point of intersection, draw $DE \perp DG$, and take $2DE$ to DG in the other given ratio. Draw GE to meet the circle at C , join AC , BC ; the $\triangle ACB$ is evidently similar to the required one.

The

The same, answered by Mr. James Whalley.

ANALYSIS: Suppose the required $\triangle ACB$ to be circumscribed by the circle $ADBI$, whose diameter DI is \perp to AB the base of the \triangle . Let O be the centre of the inscribed circle; upon AB demit the \perp s CP , OH , and draw CG , G being the middle of the base, draw also OA , OB . Now the vertical $\angle ACB$ is given, because the ratio of $AB : DI$ is given; and, the ratio of $CP : PG$ being given, the $\triangle CPG$ is given in species, hence the $\angle CGB$ is given; therefore the $\triangle ABC$ is given in species; wherefore the $\triangle OAB$ is given in species; but OH is given in magnitude, therefore the $\triangle OAB$ is given in magnitude, consequently AB is given, and a construction is evident.

Neat solutions were given to this question by Meffrs. Barr, Davis, Gregory, Hill, Lowry, May, and Swale.

IX. QUESTION 219, *answered by Miss Susan May.*

Fig. 505, Pl. 27. Let EE' be the equatorial diameter, NS the polar diameter, C the centre of the earth, and P the place where the apparent latitude is taken. Join PC and draw $PB \perp$ to the horizon at P ; then (if I rightly comprehend the proposer's meaning) there is given the $\angle EBP$, the measure of the apparent latitude, to find a simple and accurate expression for the $\angle ECP$, the latitude at the centre.

On EC demit the $\perp PA$, and draw $BF \parallel$ to PC . Then by Prop. XV. *Hutton on the ellipse*, $E'E^* : NS^* :: AC : AB :: AP : AF :: \text{tang. } \angle PBA : \text{tang. } \angle FBA$, or its equal the $\angle PCA$. Wherefore as the square of the equatorial diameter is to the square of the polar diameter, so is the tangent of the apparent latitude to the tangent of the latitude at the centre.

The same, answered by Mr. T. S. Evans, the proposer.

Let EPN be a quarter of the meridian: EC the equatorial radius which put $= a$; NC the semi-axis $= b$. Let $PB = n$ be drawn \perp to PT a tangent to P , the place whose apparent latitude is given, the sine of which put $= s$; $CA = x$, and $AP = y$;

then by the property of the ellipsis $y^* = \frac{b^*}{a^*} (a^* - x^*)$, likewise

$$a^* - x^*$$

$\frac{a^* - x^*}{x} = AT$; and $AF^* : AP^* :: AP^* : AB^*$ or $(\frac{a^* - x^*}{x})^* :$

$\frac{b^*}{a^*} (a^* - x^*) :: \frac{b^*}{a^*} (a^* - x^*) : \frac{b^* x^*}{a^*} = AB^*$; now $x^* = a^* -$
 $\frac{a^*}{b^*} y^*$, therefore substituting this for x we get $AB^* = \frac{b^*}{a^*} - \frac{b^*}{a^*} y^* :$

but $AB^* + AP^* = BP^* = \frac{b^*}{a^*} - \frac{b^*}{a^*} y^* + y^* = n^*$, and $y = sn$,

therefore $n^* = \frac{b^*}{a^*} - \frac{b^*}{a^*} sn^* + sn^*$, whence

$x = \sqrt{\frac{b^*}{a^* + b^* s^* - a^* s^*}}$, conseq. $y = \sqrt{\frac{b^* s^*}{a^* + b^* s^* - a^* s^*}}$ and

$s = \sqrt{\frac{a^* - a^* s^*}{a^* + b^* s^* - a^* s^*}}$.

Now in the $\triangle APC$, if AC be made radius, AP will be the tangent of $\angle PCA = \frac{y}{x} = \sqrt{\frac{b^* s^*}{a^* - a^* s^*}} = \frac{b^*}{a^*} \times \frac{\text{fine lat.}}{\text{cosine lat.}}$;

whence the tangent of the angle $\angle PCA$, or of the latitude reduced to the earth's centre $= \frac{b^*}{a^*} \times \text{tangent of the apparent latitude}$;

which is a very simple expression. The reader may now consult *Bezout's Navigation* at the end.

This solution being general, for any proportions of the earth's diameters, it may not be amiss to notice the present state of equations for reducing the apparent latitude to that at the centre.—By comparing the measurement of *Maupertuis* in lat. $66^{\circ} 20' N$ with that of *Maison* and *Dixon* in lat. $39^{\circ} 12' N$, we shall have the proportion of the earth's diameters $\frac{140}{177}$; that of *Maupertuis* with *Bouguer* at the equator, we shall obtain $\frac{2}{3} \frac{1}{2}$; and lastly that of *Caille* in lat. $45^{\circ} N$ with his in lat. $49^{\circ} 23' N$ we shall have the proportion $\frac{3}{2} \frac{2}{2}$; now

$\frac{140}{177} \left\{ \begin{array}{l} \text{gives the maximum of reduction of the apparent} \\ \text{latitude to that at the centre.} \end{array} \right. \left\{ \begin{array}{l} 24'. 28'' \\ 15. 23 \\ 10. 42. \end{array} \right.$
 $\frac{2}{3} \frac{1}{2} \left\{ \begin{array}{l} \text{gives the maximum of reduction of the apparent} \\ \text{latitude to that at the centre.} \end{array} \right. \left\{ \begin{array}{l} 24'. 28'' \\ 15. 23 \\ 10. 42. \end{array} \right.$
 $\frac{3}{2} \frac{2}{2} \left\{ \begin{array}{l} \text{gives the maximum of reduction of the apparent} \\ \text{latitude to that at the centre.} \end{array} \right. \left\{ \begin{array}{l} 24'. 28'' \\ 15. 23 \\ 10. 42. \end{array} \right.$
Hence

Hence it appears how uncertain we are respecting the precise quantity of this equation, and there are other proportions of the earth's diameters which run to a far greater extreme than these.— From this also appears the great utility of the present Trigonometrical Survey carrying on both in England and France.

As I do not find that *Mayer* has mentioned the proportion he used in calculating his Table pa. LXXV ; it appears, by an inverse method of calculation, that he used the proportion $\frac{230}{237}$; and *La Lande* used the proportion $\frac{229}{238}$; which is the same as *Sir Isaac Newton* found from the measurements of *Norwood*, *Picart* and the two *Cassinis* ; see the *Principia B. 3, P. 19.*

Meff's Gregory, Hill, Lowry, and Thornoby sent neat solutions to this question.

X. QUESTION 220, answered by Mr. John Lowry.

Fig. 506, Pl. 27. Through I draw IL parallel to AC, meeting AB at I., and join LH. Draw HI to meet AC at G, and CI to meet AB at M, and join HM. On HL take HO = GC, and draw OQ parallel to IH meeting MH at Q; draw also QV parallel to OH meeting CB at V. Then it is manifest, from *Prop. IV. of Professor Playfair's Paper on Porisms*, that if any two lines whatever, as HE, IE be inflected from the points H, I, to the straight line AB, and meet QV in S and AC in F, QS will be equal to FC ; and because the angle FCD is given, the triangle FCD will have a given ratio to the rectangle FC·CD, or its equal QS·CD ; therefore the rectangle QS·CD is of a given magnitude. The problem is therefore reduced to the following, viz. Through the given point H, to draw the straight line DHS so, that the sum or rectangle of QS, CD may be a given magnitude.

The first case has been done by *Simpson in his Geometry and Select Exercises*, and by *Burrow in his Diary for 1776*, and it may be done rather differently as follows. Draw HX parallel to CV, and HY parallel to QV ; then it is evident that the sum of SX and DY is given ; and by similar triangles DY : HY :: HX : SX, or $DY \cdot SX = HY \cdot HX =$ a given rectangle ; therefore the sum and rectangle of DY, SX are given to determine them, the method of doing which is well known.

The rectangle remaining constant, the sum of DY and SX will evidently be the least possible when DY is = SX, in which case the sum of QS and CD, or CF and CD will be a maximum.

The second case is the same as the celebrated problem of the Ancient Geometricians, *De Sectione Spatii*, and may be done as follows. $CD = CY - DY$ and $QS = QX - SX$; therefore $CD \cdot QS = CY \cdot QX - QX \cdot DY - CY \cdot SX + DY \cdot SX$: but $DY \cdot SX$

$DY \cdot SX$ is given, as is shewn above, it is therefore evident that $QX \cdot DY + CY \cdot SX$ is given; let this be taken $= R \times QX$, and take HW to HY as CY to QX , and draw WU parallel to DY to meet HD (produced if necessary) at U . Then, by similar triangles, it is evident that $QX \cdot WU$ is $=$ to $CY \cdot SX$, therefore $DY + WU$ is $=$ to R , and $DY \cdot WU = HX \cdot HW$. Wherefore the sum and rectangle are given to determine each, the same as before.

$DY + WU$ will be the least when SX is $=$ to WU , in which case the rectangle $CD \cdot CF$ will be a maximum.

If the ratio of CD to CF had been given, the problem would have been reduced to the *Settio Rationis* of the Ancients. Or, because CY and QV are given lines, $DY \cdot SX$ a given rectangle, and $CD : QS$ a given ratio, CD and QS may be determined by *Prop. III. Case 2nd. Geometrical Sections in the Repository*, and this perhaps suggests as simple a solution to the celebrated problem of the ancients as any that has yet been given.

The same, answered by Mr. I. H. Swale.

I. When the sum of CF , CD is given. Fig. 507, Pl. 27.

CONSTRUCTION. In the sides CA of the given $\triangle ACB$, take $CG =$ the given sum, join CH , GI , which produce to meet in P ; draw HO , PO , parallel to CB , CA meeting in O , make $ON : OH$ in the ratio of the rectangle $HC \times IP$ to $IG \times HP$, and join HN ; produce HO to AB at T , also draw PR parallel to HO meeting AB at R ; produce OP to meet AB at S , and draw IV parallel to OP meeting AB in V , and join IR .

Then, from the point T , by *Prob. 37, Simp. Geo.* draw the right line $TWQU$, meeting the given lines IR , HN , IV , in W , Q , U and making $WQ : QU = RS : SV$. Draw IQ meeting AB , AC , in E , F ; draw EH meeting BC in D , join DF , and the $\triangle EDF$ will be inscribed as required.

DEMONSTRATION. Let DE , EF , meet RP , SP , in K and L ; join KL , RL , and produce RL to meet IV at M .

By Construction,

$WQ : QU = RS : SV = RL : LM$, per the parallels SL , VM ; therefore the lines TQ , RL , are parallel; then,

$TR : RE = QL : LE = HK : KE$, per the parallels RK , TH ; and therefore the lines KL , HQ , are also parallel; wherefore

$KP : PL = HO : ON = IG \times HP : HC \times IP$, by the const.

Now, because PK is \parallel to CD , and $PL \parallel$ to FG , it follows that $IIP : HC = PK : CD$ and $IP : IG = PL : FG$; therefore $FG \times PK : CD \times PL = IG \times HP : HC \times IP = KP : PL$, from above.

VOL. III.

D

Hence

Hence $TG : CD = PK \times PL : PK \times PL$, or $FG = CD$.

Therefore $CF + CD = CF + FG = CG$ = the given sum. *Q. E. D.*

II. When the Δ FCD is of a given magnitude. Fig. 508, Pl. 27.

CONSTRUCTION. Demit upon the side AC, of the given Δ ACB, the perpendicular BR, and make $CV^* : \text{given magnitude} = BC : BR$. Join CH, CI, meeting AB at K and G; draw HS, IT, parallel to CB, CA and meeting AB at S and T; and make $CU^* : CV^* = HK \times IG : CH \times CI$. Then, by Wales' Determinate Section, cut ST at E so that $EK \times EG : ES \times ET = CU^* : SH \times TI$. Join EH, EI, meeting CB, CA, at D and F; join DF, so shall the Δ CDF be inscribed as was required.

DEMONSTRATION. Draw KL, GM \parallel to BC, AC, meeting DE, FE in L and M.—By reason of the parallels, $EK : ES = KL : SH$ and $EG : ET = GM : TI$, therefore $KL \times GM : SH \times TI = EK \times EG : ES \times ET = CU^* : SH \times TI$, by constr.

therefore $KL \times GM = CU^*$.—Now,

$CH : HK = CD : KL$ and $CI : IG = CF : GM$, therefore $CD \times CF : KL \times GM = CH \times CI : HK \times IG = CU^* : KL \times GM$;

therefore $CD \times CF = CU^*$.—But, by known properties, $CD \times CF (CU^*) : \Delta DCF = CB : BR = CU^* : \text{given magnitude}$. Therefore the ΔDCF is = the given magnitude. *Q. E. D.*

Meffrs. Cunliffe and Hill also sent neat solutions to this question.

XI. QUESTION 221, answered by Miss. Susan May.

Fig. 509, Pl. 27. Let E be the place of the earth, M that of the moon, S that of the sun, and A the point where their attractions are mutually equal. Then, by Art. 382, *Simpson's Fluxions*, the attraction of spherical bodies are directly as the quantity of matter, and inversely as the square of the distance. Consequently the ratio of the distances of the point A from the points E, M, S, will be given. Let EA, MA and SA be drawn; then because E and M are given points, and EA to MA a given ratio, the *locus* of the point A is a circle given in magnitude and position, and whose centre is in the line EM produced. And, because S is also another given point and MA to SA a given ratio, the *locus* of the point A is also another circle given in magnitude and position, and whose centre is in the line SM produced. Consequently, the intersection of these circles will determine the point A. The method of describing these circles may be seen at page 334 of *Simpson's Algebra*, and thence the calculation will also be evident.

If

If the circle HAF revolve about its diameter HF, and thereby generate a spherical superficies, it is evident that at any point whatever, in that superficies, the attraction of the earth and moon will be equal; and in like manner, if the circle LAR generate a spherical superficies by revolving round its diameter LR, any point in the superficies will be equally attracted by the sun and moon. Now, if we conceive these two superficies to intersect each other, the figure of the section will be a circle whose diameter is AB, the line joining the intersections of the circles HAF, LAR. Consequently any point whatever in the circumference of that circle is equally attracted by the three bodies.

The same, answered by Merones Minor.

Let A, B, C represent the given magnitudes of the sun, earth, and moon, respectively, and a, b, c , their respective distances from the point required. Then, the centripetal force being inversely as the square of the distance, which is the GRAND LAW OF NATURE. And, by *Emerson on Central Forces*, Prop. I: the centripetal force is as the quantity of matter in the attracting body, that is as the given magnitude in the present case. Therefore $A \div a^2 = B \div b^2 = C \div c^2$, or $\sqrt{A \div a} = \sqrt{B \div b} = \sqrt{C \div c}$, so that the question becomes, "To find a fourth point P, from whence, lines drawn to the three given points may obtain a given ratio;" which is *Simpson's 53rd. Prob. App. Alg.; or the 56th Prob. in his Select Exercises.*

XII. QUESTION 222, *answered by Merones Minor.*

Put $A = 10$ acres, $= 435600$ feet, $d = 4$, $b = 3$, $g = 16 \frac{1}{2}$, x = any variable altitude of the surface above the bottom of the apertures, and t = time sought. Then, by *Dr. Hutton's Select Exercises*, Prob. 26, $t = \frac{3A}{4b\sqrt{g}} \times \frac{\sqrt{d} - \sqrt{x}}{\sqrt{dx}}$. But when $x = 0$ this expression is infinite, as there observed; if we suppose $x = \frac{1}{2}x$, then $t = 252083''$, very near, $= 70h. 1m. 23s.$ the time of exhausting the pool to within '01 foot of the bottom of the apertures; supposing the velocity = that due to the whole altitude.

The same, answered by Miss Susan May.

This question seems designed as an example to Prob. XXVI. of *Dr. Hutton's Practical Exercises concerning forces*, where it is shewn

shewn that if x represent the variable height of the water at any time, b the breadth of the cut (3 feet), d the whole depth (4 feet). A the area of the surface of the water ($= 435600$ feet), and $g = 16\frac{1}{2}$ feet, the general time of sinking the surface to the depth x will be $\frac{3A}{2b\sqrt{g}} \times \frac{\sqrt{d} - \sqrt{x}}{\sqrt{dx}}$. But when x is 0 this

expression is infinite, which shews that the water can never be exhausted so as to be on a level with the bottom of the aperture.

By taking $x = \frac{1}{144}$, we obtain, by substituting, the particular values in the above expression, the time of exhausting to $\frac{1}{144}$ of an inch of the bottom $= 624551''$ nearly. Now this is the time of exhausting through one of the apertures: but since an equal quantity is discharged through each, the time will be only one half of that above, that is $= 312275'' \cdot 5 = 86h. 34m. 35\frac{1}{2}s.$

Mr. GREGORY of Cambridge also refers to the same problem in Dr. Hutton's *Select Exercises*, and adopts the general expression

$$t = \frac{3A}{4b\sqrt{g}} \times \frac{\sqrt{d} - \sqrt{x}}{\sqrt{ax}}$$
, for the time of sinking the surface

to the depth x in both apertures, whence when $x = \frac{1}{1000}$ he deduces the value of $t = 252082 \cdot 88''$. He then observes that when one value of t is thus found, others may be readily ascertained, since they will vary as $\frac{\sqrt{d} - \sqrt{x}}{\sqrt{x}}$. Thus when $x = \frac{1}{1000}$,

$$\frac{\sqrt{d} - \sqrt{x}}{\sqrt{x}} = 93 \cdot 868328; \text{ but when } x = \frac{1}{1000},$$

$$\frac{\sqrt{d} - \sqrt{x}}{\sqrt{x}} = 19: \text{ therefore, as } 19 : 93 \cdot 868328 ::$$

$252082 \cdot 88'' : 1245400 \cdot 97174'' = 345h. 56m. 40 \cdot 97s$, time of exhausting to the depth of $\frac{1}{1000}$ of a foot.

The same, answered by Mr. John Barron, Spilsby.

Put $d =$ the depth of the apertures, $b =$ the breadth of one of them, $g = 16\frac{1}{2}$, $a =$ area of the pool, and $x =$ any variable altitude of the water above the bottoms of the apertures. Then by the Principles of Hydrostatics $2\sqrt{gx} =$ the velocity of the effluent

effluent water, and $2bx\sqrt{gx}$ will, therefore, express the fluxion of the quantity of water issuing through one of the apertures in a second of time. The fluent of which is $\frac{4bx}{3}\sqrt{gx}$, the quantity of water issuing through one of the apertures in a second; wherefore, $-ax \div \frac{4bx}{3}\sqrt{gx} = \frac{3a}{4b\sqrt{g}} \times \frac{-x}{x^{\frac{3}{2}}} =$ the fluxion of the time, the fluent of which is $\frac{3a}{2b\sqrt{gx}}$. But when $x = d$, the time is nothing, therefore the correct fluent is

$\frac{3a}{2b\sqrt{g}} \left(\frac{1}{\sqrt{x}} - \frac{1}{\sqrt{d}} \right) =$ the time through one of the apertures, and therefore $\frac{3a}{4b\sqrt{g}} \left(\frac{1}{\sqrt{x}} - \frac{1}{\sqrt{d}} \right) =$ the time through both apertures. Now when $x = 0$, this expression for the time becomes infinite, which shews that the surface of the water in the pool can never arrive at the level of the bottoms of the apertures.

And thus the question was answered by Mr. Cunliffe. It was also answered by Messrs. Bosworth, Davis, Hill, and Lowry.

To XIII. QUESTION 223, we have received no answer.

XIV. QUESTION 224, answered by Mr. James Cunliffe.

Let ABC (fig. 510, pl. 27.) be the Δ , O the centre of its inscribed circle, through which and the angular points A and C draw the right lines AE, CD to terminate in the opposite sides BC, AB. These lines, as is well known, will bisect the respective angles CAB, and ACB. Let the parts of the weight sustained by the fulcrums at the respective angular points be denoted by A, B, and C. It appears from *Emerson's Mechanics, Prop. 43, Sect. 5*, that O is the common centre of gravity of the parts of the weight sustained by each of the fulcrums: moreover it appears from Prop. 45, of the same, that D is the centre of gravity of the parts denoted by A and B; and E that of the parts denoted by B and C. Wherefore, since CD bisects the $\angle ACB$, by the nature of the centre of gravity and Euc. 3. VI.

$AC : CB :: AD : DB :: B : A$, whence

$A = (BC \div AC) \times B = \frac{4}{5}B$. And for the same reason

$AC : AB :: B : C = (AB \div AC) \times B = \frac{1}{5}B$.

Then by the question $A + B + C = \frac{4}{5}B + B + \frac{1}{5}B = \frac{8}{5}B = 100$.
Whence $B = 37\frac{1}{4}$ lb, $A = \frac{4}{5}B = 30$ lb, and $C = \frac{1}{5}B = 7\frac{1}{4}$ lb.

When each of the props sustain an equal part of the weight, the point O, the place thereof, will be determined by the intersection of the lines CD, AE drawn to bisect AB, BC, in the points D and E respectively.

If O, the place of the weight, be any other given point within the $\triangle ABC$, the parts of the weight sustained by props at each of the angular points may be determined as follows, *viz.* by drawing through the given point the right lines CD, AE from the \angle s C and A to the opposite sides. For it is evident from the above quoted authority that D is the centre of gravity of the parts A and B, and E that of the parts B and C, the ratios of which hence become known.

The same, answered by Mr. Gregory, the proposer.

In the solution of this question it is necessary, in the first place, to enquire, when a plane triangle is supported by three fulcra at the angular points, and a weight W is laid upon it at any other point, what is the ratio of the pressures on each fulcrum? To ascertain this, let ABC (fig. 511, pl. 27.) be the triangle, and D the point where the weight is placed; produce BD to F, and from the points B and D let fall the perpendiculars BH, DG, upon the side AC. Then, if we suppose the triangle to revolve about AC as an axis, the point F may be considered as a fulcrum to the power P at B, and weight W at D: therefore, $P : W :: DF : BF :: DG : BH$, by similar triangles. Consequently $P = \frac{DG \times W}{BH}$. But W and BH are constant, therefore $P \propto DG$,

and of course $P \propto DG \times AC$, or $\propto \frac{DG + AC}{2}$; that is, the

pressure at B is as the area of the triangle DAC opposite. In the same manner it might be shewn, that the pressures at A and C, are as the areas of the triangles BCD and BAD respectively.

Hence, the first requisite of the question is easily determined: for when the weight is laid at D the centre of the inscribed circle, the perpendiculars DF, DI, and DL, let fall on the sides, will be equal to each other, and the areas of the triangles ACD, ABD, BCD, will be as their bases AC, AB, BC; therefore, by what has been shewn above, the pressure upon the angles A, B, C, will be as BC, AC, and AB, or as 26, 30, and 24 respectively.

It is also manifest from the foregoing, that, when the pressure is the same on each fulcrum, the point D must be so chosen that lines drawn from it to the angular points shall divide the triangle into three equal parts. In this case the point D may be found by the following.

CONSTRUCTION: Bisect AB in the point E by the line CE, make $AP = \frac{1}{3}AC$, and draw PK parallel to AB: the point D in which CE and PK intersect each other, is the point required. For, since $CP = \frac{2}{3}AC$, and the triangles CPD, CAE are similar; similar triangles being as the squares of their homologous sides, we have $CPD = \frac{4}{9}CAE$, also, since $AP = \frac{1}{3}PC$, and the triangles APD, CPD, are between the same parallels, $APD = \frac{1}{3}CPD = \frac{4}{9}CAE$: therefore ACD, the sum of these, $= \frac{5}{9}(\frac{1}{3})CAE$, or $\frac{5}{27}ABC$, the whole triangle being bisected by the line CE. In like manner, since CK $= \frac{2}{3}BC$, it might be shewn that the triangle CDB $= \frac{1}{3}ABC$; and consequently ADB, the remaining triangle, $= \frac{1}{3}ABC$; and the three triangles formed by lines drawn from D to the angular points, are equal to each other.

To determine the point D by **CALCULATION**, first find the area of ABC, which as performed by a well known rule, is 299.33259094: this divided by $\frac{1}{3}CA$ gives 19.955506 $= BH$. Also $(\frac{1}{3} \text{ area} \div \text{ by } \frac{1}{3}CA) = 6.651835 = DG$; $(\frac{1}{3} \text{ area} \div \text{ by } \frac{1}{3}AB) = 8.314794 = DI$; $(\frac{1}{3} \text{ area} \div \text{ by } \frac{1}{3}BC) = 7.675194 = DL$. Then, by reason of the parallels DP, BA, — DG, BH, we have, $BH : DG :: 3 : 1 :: BA : DP = 8$. Again $\sqrt{(DP - DG^2)} = 4.44444497 = GP$; wherefore, $GP + AP = AG = 14.444445$ nearly. And $\sqrt{(GA^2 + GD^2)} = AD = 15.90248097$, by which we have determined D, since AP and DP are known. The distances BD and CD may be found by means of 47, Euc. I. AB, BC, DI and DL, as well as AD, being known; as may be readily traced out, by those who have leisure and inclination to pursue the operation through all the requisite steps.

N. B. To avoid the imputation of plagiarism it may be proper to remark that the above construction for the point D, is nearly similar to one given in No. 11, of the Scientific Receptacle; but as the truth of the construction is not demonstrated in that work, I have here supplied the deficiency.

The same, answered by Merones Minor.

Fig. 510, Pl. 27. Bisect the \angle s A, B, C, of the given \triangle by the lines AE, BF, CD, and their intersection, O, will be the place of the weight. Then whether the weight be supported at A, B, and C, or only at A and E, the pressure at A will be the same;

same; and which, by *Em. Mech.* 31, *Cor. 2. 800*, is $= \frac{100EO}{AE}$

$= \frac{100BE}{AB+BE} = \frac{100BC}{AB+BC+AC}$, *ibid. Geom.* 25, 2nd and 13. *Proprietas*, $=$ 30 lbs. In like manner, the pressure at B $= \frac{100AC}{AB+BC+AC} = 32\frac{1}{2}$ lb, and that at C $= \frac{100AB}{AB+BC+CA} = 37\frac{1}{2}$ lb.

He also observes that in the second case, as the pressures are to be equal, the distances must be equal also; so that the centre of the circumscribing circle will be the point required, and its distance from each of the angular points $= 15.6344$.

This question was ingeniously unanswered by Mrss. Barron, Buffham, Davis, Hill, May, and Lowry.

XV. QUESTION 225, answered by Mr. Cunliffe.

Multiplying the terms of the series by x and taking the fluents, there will be had,

$$h. l. (1+x) + h. l. (1+x^2) + h. l. (1+x^4) + h. l. (1+x^8) \&c.$$

ad infinitum: put $= h. l. (y)$; then by the nature of logarithms,

$(1+x) \times (1+x^2) \times (1+x^4) \times (1+x^8) \&c. = y$; this last expression being actually multiplied becomes

$$1+x+x^2+x^3+x^4 \&c. = y. \text{ But it is well known that}$$

$$1+x+x^2+x^3+x^4 \&c. = \frac{1}{1-x}, \text{ and therefore}$$

$$(1+x) \times (1+x^2) \times (1+x^4) \times (1+x^8) \&c. = \frac{1}{1-x}. \text{ In which}$$

expression, writing x^n in the place of x it becomes

$$(1+x^n) \times (1+x^{n+1}) \times (1+x^{n+2}) \times (1+x^{n+3}) \&c. =$$

$$\frac{1}{1-x^n}:$$

but $1+x^n$, is the $(n+1)$ th factor of the foregoing continued product; therefore dividing the former expression by the latter there will be had

$$(1+x) \times (1+x^2) \times (1+x^4) \times (1+x^8) \&c. \text{ to } n \text{ factors} =$$

$$\frac{1}{1-x}$$

$\frac{1-x^n}{1-x}$, whence by the property of logarithms,

h. l. $(1+x) +$ h. l. $(1+x^2)$ h. l. $(1+x^4)$ &c. to n terms =

h. l. $(1-x^{2^n}) -$ h. l. $(1-x)$.

Taking the fluxions of this expression and dividing by x we get

$\frac{1}{1+x} + \frac{2x}{1+x^2} + \frac{4x^3}{1+x^4} + \frac{8x^7}{1+x^8}$ &c. to n terms = $\frac{1}{1-x} -$

$$\frac{2^n \times x^{2^n} - 1}{1-x^{2^n}}.$$

And thus the question was answered by Mr. Whalley. Other answers were received from Messrs. Gregory, Hill, Lowry, May, Peacock, and Thornoby.

XVI. QUESTION 226, answered by Mr. Gregory, the proposer.

In order to solve this question, let the radius of either wheel be denoted by r , its weight by w , the radius of either axle by d , and the weight suspend from it by p : then, according to Prob. 15,

pa. 40. Banks's Treatise on Mills, we have $\frac{dpr}{r^2w + d^2p}$ for the accelerating force at the circumference, that of gravity being 1;

this being drawn into $16\frac{1}{2}$ produces .2007280288 for the velocity of the circumference of the wheel: and, as $r : d$, or as $2 : \frac{1}{4} :: .2007280288 : .0250910036$, velocity of the circumference of the first axle, or space passed over by the weight suspended from it in the first second; let this be denoted by a . Again, in the second

wheel, $\frac{.25 \times 5 \times 1.75}{(3.0625 \times 40) + (0.625 \times 5)} = .0178131543$ is the accelerating force at the circumference; which drawn into $16\frac{1}{2}$ gives .2864948984, velocity of the circumference of the wheel; also, as $r : d$, or as $1\frac{1}{4} : \frac{1}{4} :: .2864948984 : .0409278426$ velocity of the circumference of the second axle, or space passed over by the weight suspended from it in the first second; let this be represented by b . Then, putting x for the space descended by the first weight in the whole time, by the nature of descending bodies,

we have $a : x :: 1^o : \frac{x}{a}$, square of the whole time; and, by the

question

question $b : x + 50 :: 1^2 : \frac{x + 50}{b}$, square of the whole time

also; therefore, $\frac{x}{a} = \frac{x + 50}{b}$, whence $x = \frac{50a}{b-a} =$

$\frac{125455018}{015836839} = 79.2165774$ feet. Consequently, 0250910036

$: 79.2165774 :: 1^2 : 8157.17053422$, the square of the time, and 56.18870468 seconds, the time required.

Or the time might be found rather more concisely, by saying, as 015836839 (the difference between the distances described by the weights in the first second): 50 (the given difference) $:: 1^2 : (56.1887)^2$ which gives the time of description as before. — Other methods of calculation give 56.19 for the result, corresponding nearly with the above.

The same, answered by Miss Susan May.

Put W = weight of the greater wheel; = 50 lb. and R = its radius = 2 ft.

w = weight of the lesser wheel, = 40 lb; and r = its radius = $1\frac{1}{4}$ ft.

a = rad. of the axle = $\frac{1}{2}$ ft. and b = weight suspended therefrom = 5 lb.

$g = 16\frac{1}{2}$ feet, and t = time required.

Then, because the weight of the wheels is supposed to be condensed into their circumferences it follows from Prop. XIX. Sec. VI. of *Atwood's Treatise on Motion* that the accelerative force at the circumference of the axle of the greater wheel is =

$\frac{a^2 b}{WR^2 + a^2 b} = \frac{1}{8+4} (= p)$; and that the accelerative force at the

circumference of the axle of the less wheel is = $\frac{a^2 b}{wr^2 + a^2 b} =$

$\frac{1}{7\frac{1}{3}} (= q)$. And by Prop. IV. Sec. III. Cor. 5, *ibid*, the space descended by the weight attached to the greater wheel is = gpt^2 and the space descended by the other weight is = gqt^2 . Therefore

$g(q-p)t^2 = 50$, or $t = \sqrt{\frac{50}{g(q-p)}} = 56.19$ nearly, for the time required.

Ingenious solutions were also received from Messrs. Bosworth, Davis, Hill, Lowry, and Merones Minor.

XVII. QUESTION 227, answered by Mr. Cunliffe, the pro. eser.

Let ACB represent the triangular plot of land, with the perpendiculars DD , BF , and AE as per figure 512; plate 27.

Put $AC=a$, $AD=c$, $CB=b$, and $BD=d$. Then there will be had

$$a^2 - c^2 = b^2 - d^2 = CD^2, \text{ or } (a+c) \times (a-c) = r \times (b+d) \times (b-d)$$

$$\div r = CD^2$$

put $a+c=r \times (b+d)$ then $a-c=(b-d) \div r$; from these equations

$$a = \frac{r^2 \times (b+d) + d - b}{2r}, \text{ and } c = \frac{r^2 \times (b+d) + b - d}{2r}$$

Now $b^2 - d^2 = CD^2$, must be a rational square; therefore put $r \times (m^2 + n^2) = b$, and $r \times (m^2 - n^2) = d$, then will

$$a = \frac{r^2 \times (b+d) + d - b}{2r} = r^2 m^2 + n^2; \text{ and } c = \frac{r^2 \times (b+d) + b - d}{2r} = r^2 m^2 - n^2$$

from whence $AB = AD + DB = c + d = (r+1) \times (rm^2 - n^2)$, where r , m , and n , may be taken at pleasure.

Therefore take $r=2$, $m=3$, and $n=2$; then $CB=r \times (m^2 + n^2) = 26$, $BD=r \times (m^2 - n^2) = 10$, $AC=r^2 m^2 + n^2 = 40$, and $AB=(r+1) \times (rm^2 - n^2) = 42$: but as each of these is divisible by 2, we may take $CB=13$, $BD=5$, $AC=20$, and $AB=21$.

Then by the similar triangles ACD , and ABF

$$AC : AD :: AB : AF = (AD \times AB) \div AC = (16 \times 21) \div 20 = 16^4,$$

whence $AC - AF = CF = 8^1$. Also by the sim. Δ s CBF , CAE , $CB : CF :: CA : CE = (CF \times CA) \div CB = 64 \div 13$.

Wherefore, reducing the numerical values of AC , BC , FC , and EC to a common denominator, there will be had

$$AC = \frac{20 \cdot 13 \cdot 5}{13 \cdot 5} = \frac{1300}{65}, \quad BC = \frac{13 \cdot 13 \cdot 5}{13 \cdot 5} = \frac{845}{65}, \text{ and } AB =$$

$$\frac{21 \cdot 13 \cdot 5}{13 \cdot 5} = \frac{1365}{65}.$$

Therefore rejecting the common denominator 65, there may be taken $AC = 1300$, $BC = 845$, and $AB = 1365$; and these are the numerical values of the sides of a triangle whose perpendiculars and segments of the sides made thereby are all whole numbers. The above numbers seem to be the least for an acute angled triangle, or one whose perpendiculars fall within it: but if we admit

mit an obtuse angled triangle the side AB' will be 715, and is found by taking the segment DB' from D towards A .

These are the least numbers of the kind that I have hitherto found; however they may not be the least, as perhaps a different process might discover others that are less. An isosceles triangle of less dimensions might readily have been found that would answer; but that is not what was meant.

Messrs Gregory, Lowry, and Miss May, also favoured us with neat solutions to this question.

XVIII. QUESTION 228, answered by Mr. John Andrew, Cork.

ANALYSIS. Fig. 513. Pl. 27. Suppose the thing done, B and H the given points, CD the line given in position, CHI the given angle, and $BCHI$ the circle required, the centre of which is O . Join the given points B, H , with the straight line BH , which bisect at A by the $\perp AG$, meeting CD in G , which is a given point, and AG a given line. From A and O , upon CD drop the $\perp s AP, OP'$, and draw the radii CO, HO and IO , parallel to which draw AD .

The $\angle COI = \angle CHI$ (Euc. 20. III.), theref. the $\angle COP' = P'OI = CHI = PAD$, wherref. PAD is $=$ the given \angle , and AD a given line. Moreover the right $\angle d \Delta s 1P'0$, DPA are equiangular, and so are the $\Delta s GOI, GAD$; hence $AG : AD :: GO : OI = OH : but AG$ and AD are given lines, theref. the ratio of $OG : OH$ becomes known. Now, G and H being given points, the centre O may be found by the following

CONSTRUCTION. Having found the points A, G , and D , as in the *Analysis*, join GH , and from A to GH produced, apply $AQ = AD$; also draw HO parallel to the line joining the points A and Q , to meet AG at O , the centre of the inscribed circle.

The same, answered by Mr. Lowry.

CONSTRUCTION. Fig. 514. Pl. 27. Let A and B be the given points, and CD the straight line given by position. Bisect the line adjoining the points A, B , at F , and draw $FO \perp$ to AB meeting CD in O . On CD demit the $\perp FH$, and draw the FS to make the $\angle hFS =$ to the given \angle , and meet CD at S . In a semicircle described on the diameter AO , apply $OQ =$ to a 4th proportional to SF, OF and AF . Draw AQ to meet FO at G ; so shall G be the centre of the required circle.

Join

Join A, G ; G, D ; A, D ; and A, C ; and on CD demit the \perp . GI. It is evident that the Δ s AFG, GOQ are equiangular ; theref.

$AG = GD : AF :: GO : OQ$, but by construction,

$SF : OF :: AF : OQ$; therefore, by equality,

$GD : GO :: SF : OF$; wherefore GD is parallel to SF. Consequently the $\angle CAD = DGI = SFH =$ the given \angle by const.

The same, answered by Mr. L. H. Swale.

Fig. 515, Pl. 27. Suppose the circle described through the given points A, B, as required, and cutting the indefinite right line CD in the points C, D. Join BA, BC, BD ; draw DE \parallel to BA meeting the circle at E, and join CE.

Then, since the $\angle DBC = DEC$, and $\angle EDC = BPC$, are given, the $\angle DCE$ will also be given. Bisect AB at G, by the \perp FGH, meeting CD, DE in F and H, then will $DH = HE$; therefore $DF : FC$ is a given ratio ; for, from above, the Δ DCE is given in species. Consequently, since, the reft. $CP : PD = AP : PB$, and the line FP are given we have the following

CONSTRUCTION. Let the right line BA, joining the given points B and A, meet the indefinite right line CD, given in position, in P. Bisect BA in G and draw GF \perp to BA to meet CD at F ; draw FK to BA making the $\angle FKP =$ the given one ; and bisect PK at L. Draw PQ \perp to CD and $=$ to the side of a square $=$ to the reft. $BP : PA$; join QF ; make FI : FQ $=$ LG : LP (LK), and on QI describe a semicircle cutting CD in C ; then through A, B and C, describe a circle, and it is done.

DEMONSTRATION. Let the circle meet CD again in D ; join BC, BD ; IC, QC, QD ; draw DE \parallel to BA to meet the circle at E, join CE, produce FG to meet DE at H, and let LR, drawn \parallel to GF, meet PF at R.

By constr. $PQ^2 = PB \cdot PA = PC \times PD$, and $PQ \perp$ to CD ; therefore the points D, Q, C are in a semicircle, or $CQ \perp$ to QD. But by constr. the points I, C, Q, are in a semicircle, or $CQ \perp$ to CI. theref. CI, DQ, are parallel ; and therefore

$FC : FD = FI : FQ = LG : LB$, by constr. $= RF : RP$, by \parallel s ; also $DH : HE = PL : LK$, i.e. $DC : PF = CE : FK$, or CE is \parallel to FK. Hence, $\angle PKF = DEC = DBC$ by the circle = the given \angle by constr.

The same, answered by Mr. James Whalley.

ANALYSIS. Fig. 516, Pl. 27. Suppose the circumference of the circle to pass through the two given points E and A, and to cut the line FG given by position in the points F, and G,

so that drawing FE , GE , the $\angle FEG$ may be of a given magnitude. Draw the right line EA cutting FG in I , and suppose GO to be a tangent to the circle at G meeting EA produced in O . Then, by Euc. 36. III. $OA \times OE = OG^2$, and, by Euc. 32. III. the $\angle IGO = FEG =$ a given \angle , also the $\angle GIO$ is given from the position of FG , whence the $\triangle IGO$ is given in species, and therref. the ratio of OG to OI , or of $OG^2 = OA \times OE$ to OI^2 , is given. Now, E , I , and A are given points in the indefinite right line EO , therref. the point O may be found by Prob. 6, of Wales's *Determinate Section*, and belongs to fig. 20, of that problem.

Ingenious Solutions to this question were also received from Messrs. Cunliffe, Hill, May and Peacock.

XIX. QUESTION 229, answered by the proposer, Mr. Robert Wallace.

Let $EBHCGF$ (fig. 541, pl. 28.) be a paraboloid, and A a corpuscle of matter situated in the axis produced. Put $AD = y$, $AH = a$, $AB = z$, $y - a = HD$, therref. $y^2 + DC^2 = AC^2 = z^2$, $b(y - a) = DC$ (b , being the latus rectum), that is $by - ab = z^2 - y^2$, therref. $y^2 + by = z^2 + ab$, and therref. $y^2 + by + \frac{1}{4}b^2 = z^2 + ab + \frac{1}{4}b^2$; hence $y = \pm \sqrt{(z^2 + ab + \frac{1}{4}b^2)}$

$$- \frac{1}{2}b, \dot{y} = \frac{zz}{\sqrt{(z^2 + ab + \frac{1}{4}b^2)}} : \text{ put } ab + \frac{1}{4}b^2 = g^2$$

$$\text{then } \dot{y} = \frac{zz}{\sqrt{(z^2 + g^2)}}.$$

Now the attraction of all the particles in the circular surface BDC (vid. Simpson's *Fluxions*, Vol. 2d. Art. 376,) is $= (AD \times AB^{n+1} - AD^{n+2}) \times [2P \div (n+1)]$, P , being $= 3.14159$, &c. Therefore by substituting and fluxing

$$\text{we obtain } (y\dot{y}z^{n+1} - y^{n+2}\dot{y}) \times [2P \div (n+1)]$$

$$= [(\sqrt{z^2 + g^2} - \frac{1}{2}b) \times \frac{zz}{\sqrt{(z^2 + g^2)}} \times z^{n+1} - y^{n+2}\dot{y}] \times \frac{2P}{n+1}$$

$$= [(zz - \frac{bzz}{2\sqrt{(z^2 + g^2)}}) \times z^{n+1} - y^{n+2}\dot{y}] \times \frac{2P}{n+1}$$

$$= (z$$

$$= (z^{n+2} - \frac{bz^{n+2}z}{2\sqrt{(x-g^2)}} - y^{n+2}y) \times \frac{2P}{n+1} = \text{the fluxion of}$$

the whole force, the whole fluent of which, being found by Simpson's first volume, and corrected will give the whole force of the attraction of the paraboloid, &c.

XX. QUESTION 230, answered by the proposer, Mr. Cumliffe.

Denote the required fractions by $\frac{\frac{1}{4}x}{x+y}$ and $\frac{\frac{1}{4}y}{x+y}$; for upon trial it will be found that if either of them be added to the square of the other, the sum thence arising will be a rational square. Therefore it only remains to determine such values for x and y as shall make the sum of the squares and the sum of the cubes of the above fractions rational squares,

$$\text{viz. } \frac{1}{16} \times \frac{x^2+y^2}{(x+y)^2} \text{ and } \frac{1}{64} \times \frac{x^3+y^3}{(x+y)^3} = \frac{1}{64} \times \frac{x^2-xy+y^2}{(x+y)^2} \text{ each}$$

a square; or which amounts to the same thing, x^2+y^2 and x^2-xy+y^2 , must each be a square.

Put $2mn = x$ and $m^2-n^2=y$, then $x^2+y^2=(m^2+n^2)^2$, which is manifestly a square: also $x^2-xy+y^2=m^4-2m^2n+2m^2n^2+2mn^2+n^4=m^4-2m^2n+2m^2n^2+2m^2n^2+n^4=(m^2-mn+n^2)^2=m^4-2m^2n+3m^2n^2-2mn^3+n^4$, which being reduced gives $m=4n$; wherefore $x=2mn=8n^2$, and $y=m^2-n^2=15n^2$; whence $\frac{\frac{1}{4}x}{x+y}=\frac{8}{92}$ and $\frac{\frac{1}{4}y}{x+y}=\frac{15}{92}$, which are two

fractions that will answer the conditions of the question.

The same question answered differently.

Let $\frac{1}{4} - x$ and x denote the two required fractions;—for it will be found that either of them being added to the square of the other will make a rational square.

It therefore only remains to find the value of x , so that the sum of the squares, viz. $\frac{1}{16} - \frac{x^2}{2} + 2x^2$, and the sum of the cubes,

viz. $\frac{1}{64} - \frac{8x}{16} + \frac{3x^2}{64}$, of the two fractions may both be square

numbers; or, which is the same thing, that $1 - 8x + 3x^2$ and $1 - 12x + 48x^2$, may each be a square number. Assume $4nx - 2$ for the root of the former of these, that is, put $1 - 8x + 3x^2 = (4nx - 1)^2 = 16n^2x^2 - 8nx + 1$, which gives $x = \frac{n-1}{2(n^2-2)}$;

this being written for x in the other expression $1 - 12x + 48x^2$, it becomes $1 - \frac{6(n-1)}{n^2-2} + \frac{12(n-1)^2}{(n^2-2)^2} = \frac{1}{(n^2-2)^2}$

$\times (n^4 - 6n^3 + 14n^2 - 12n + 4)$, which must be a square number by the question, therefore $n^4 - 6n^3 + 14n^2 - 12n + 4$ must be a square. Assume $n^2 + 8n - 2$ for its root, or make $n^4 - 6n^3 + 14n^2 - 12n + 4 = (n^2 + 3n - 2)^2 = n^4 + 6n^3 + 5n^2 - 12n + 4$, which being reduced gives $n = \frac{1}{2}$; therefore $x = \frac{n-1}{2(n^2-2)} = \frac{1-n}{2(2-n^2)} = \frac{8}{2} = 4$, and $\frac{1}{4} - x = \frac{1}{4} - \frac{8}{2} = \frac{15}{8}$, which

are the very fractions obtained by the other method of solution.

Mr. Lowry and Miss May likewise find solutions to this question.

XXI. QUESTION 231, answered by Mr. James Whalley.

Fig. 517, Pl. 27. *Anylasis.* Let ABCD represent the trapez. AB the given side, P the given point therein, through which the side CD, opposite to the given side AB, passes; CAB the given \angle , and QE the right line given by position, in which is situated the angular point D opposite to the given \angle A. Produce AC to meet QE in E, and draw BF \parallel to QE meeting AE in F and join FD, DB.

The area of the \triangle FEB = \triangle FDB, by Euc. 37. I. theref. \triangle AEB = trap. AFDB = a given space. But the area of the trap. ABCD is given by the question. Wherefore the area of the \triangle CFD becomes known. Whence the following

CONSTRUCTION by Mr. James Cunliffe.

Draw the right line PF, and produce AF, so that the area of the \triangle FPS may be = to the given space CFD; through S draw an indefinite right line SN parallel to PF. Then through P draw

draw the right line NPCD by Prob. 37, *Simpson's Geometry*, so that $PN = CD$, and the thing is done.

The same, answered by Mr. I. H. Swale.

Fig. 517, Pl. 27. Suppose the trap, ABCD determined as required, AB the given side, BAC the given \angle , P the given point in BA produced, DC the side passing through P, and DE the right line given in position, in which the $\angle BDC$, or the point D is posited: Produce AC to meet DE at E and join EB meeting PD in Q', then will the point E be given, therefore the ΔAEB will be given in magnitude: but the trap. ABCD is also given, theref. their difference, or the difference of the Δ s $CQ'E$, $DQ'B$ will be given; theref. by adding common space $DQ'E$ to each, the difference between the areas of the Δ s DEC, DEB will be given; and, since the base DE is common to those Δ s, the rectangle. under DE, and the difference of the \perp s from C and B upon DE, will be given: Now, draw CG, BF \perp to DE, and BF \parallel to FD, meeting CG in H. Then, since $BF = GH$, it follows that $CH \times DE$ is a given rectangle. Draw $BE' \parallel$ to AE, the Δ s $BE'F$, CHF are similar, theref. $CF : CH = BE' : BF$, a given ratio, whrcf. the rect. $CF \times ED$ is given. Now E and F are given points, and ED, EA straight lines given by position, and P being also a given point, the problem is, therefore, reduced to the *sectione spati* of the Aclients.

The same, answered by Mr. Lowry.

Fig. 518, Pl. 27. CONSTRUCTION. Let AB be the given side, P the given point, and ZL the straight line given by position. Draw AC to make the given \angle with AB, and on AB constitute a parallelogram BAGK = to twice the given area. By Prob. 37 of *Simpson's Geometry*, draw PI to meet AC in C, ZL in D, and GK produced in I, so that CD may have to CI the given ratio of AB to PB. Join BD, and ABCD will be the trapezium required.

Through C and D let CE, VDF, be drawn \perp to AB, and \parallel to AB, let CQ be drawn, meeting DF in Q.

Then by reason of the parallels,

$QD : QV :: CD : CI :: AB : PB$, by construction; therefore, $QD \cdot PB = QV \cdot AB$, and, by adding $CE \cdot AB$ to each, we have $QD \cdot PB + CE \cdot AB = (QV + CE) \cdot AB =$ the paral. BG. Again, $PB \cdot DF = PB \cdot (EC + QD) = 2 \Delta PDB$, and

$PA \cdot CE = CE \cdot (PB - AB) = 2 \Delta PAC$; therefore, their difference $QD \cdot PB + CE \cdot AB =$ trap. ABCD = parallelogram BAGK.

Consequently the trapezium is equal to the area. The rest is evident from the construction.

XXII. QUESTION 232, *answered by Mr. Lowry.*

Fig. 519, Pl. 28. Let ABCD be a trapezium inscribed in the circle ABCDEF; draw the diameter FHE \perp to one of the diagonals as AC, and on the opposite sides AB, DC, demit the \perp s EL, FK. Draw, BG, DI, \parallel to AC, to meet EF at G and I, and join A, F; A, E; D, E; D, F; B, E; C; E; and CF.

Then by the similar triangles AFE, LBE, $AF \cdot EF :: LB \cdot BE$, that is, (by Simpson's Geom. Cor. to 19. VI.) $FE \cdot FH \cdot EF :: LB \cdot FE \cdot EG$; therefore $LB = GE \cdot FH$.

In a similar way it is shewn, from the sim. Δ s KDF, CEF, that $DK = EH \cdot FI$, and, from the sim. Δ s ALE, FGB, that $AL = EH \cdot FG$; and also, from the sim. Δ s CKF, EID, that $CK = FH \cdot EI$. Therefore

$LB = CK = FH \cdot IG$, and $DK = AL = EH \cdot IG$.

Again, by the circle, $FH : AH :: AH : EH$, therefore $FI \cdot IG : AH \cdot IG (= \text{trapez. } ABCD) :: AH \cdot IG : EH \cdot IG$, or $* LB = CK : \text{trap. } ABCD :: \text{trap. } ABCD ; DK = AL$.

Now it is evident that LB is $=$ to half the sum of the sides AB, BC, and DK $=$ half the sum of the sides AD, DC; theref. $LB + DK$ is $=$ to half the perimeter, and conseq. the excesses of half the perimeter above each of the sides AB, BC, DC and AD, are $DK - AL$, $DK + AL$, $LB - KC$, and $LB + KC$, respectively. But by cor. 1. 9. H. Simpson's Geometry, $(LB - KC) \cdot (LB + KC) = LB^2 - KC^2$, and $(DK - AL) \cdot (DK + AL) = DK^2 - AL^2$,

therefore it is manifest from what is proved above * that the trapezium is a mean proportional between the rectangle under the excesses of half the perimeter above two of the sides, and rectangle under its excesses above the other two sides, which is the rule alluded to in the question.

The proportion marked thus * suggests another rule for finding the area, which will on many occasions be found more commodious than that given above.

XXIII. QUESTION 233, *answered by Mr. Cunliffe,*

Fig. 520, Pl. 28. In any plane Δ ACB inscribe a circle, touching the base AB in T, and the other two sides in Q and R. Draw the right line CI to bisect the base in I, and through the centre O of the circle draw the right line TP to meet CI in P;— through P draw ab parallel to AB, to meet the sides AC, BC in a and b respectively; and draw Oa, Ob, OQ, OR.

Since

Since ab is parallel to AB it will be bisected by CI in P ; of $aP = Pb$. Now TP is \perp , or at right angles, to AB , by Euc. 18. III.; therefore PO is \perp to ab , by Euc. 28. I.; wheref. the $\triangle aOb$ is isosceles, or $aO = Ob$; but $OR = OQ$, and $\angle OQa = ORb =$ a right \angle , by Euc. 18. III.; theref. $\angle bOR = aOQ$, by Euc. 4. I.

Because $\angle OPb = ORb =$ a right \angle , a circle will pass through the points O, P, b, R , and therefore $\angle bOR = bPR$, by Euc. 21. III. For the same reason a circle will pass through the points O, P, Q, a , and therefore $\angle aOP = aPQ$, consequently $\angle bPR = \angle aPQ$; therefore the points Q, P, R are in the same straight line, by Euc. 15. I.

The same, answered by Mr. Lowry.

Fig. 520, Pl. 28. Let ACB be the \triangle , CI the line bisecting the base, O the centre of the inscribed circle, OP a part of its diameter drawn from the point where it touches the base; and R and Q the other points of contact. About the \triangle describe a circle, and let the diameter XIE be drawn \perp to the base; also let CE be joined, which will pass through O , the centre of the inscribed circle. Now, if the line joining the points R and Q meets OP at P , the truth of the proposition will appear manifest if we can prove the points I, P, C to be in a straight line. In order to do this, through I , draw $GIH \parallel$ to RQ to meet the sides at G and H , also draw $AY \parallel$ to BC to meet IG produced at Y , and join GE . Then because $RC = CQ$, CG will be \parallel to GH , also AY is \parallel $AG = BH$; theref. AG is \parallel half the diff. of the sides AC, CB ; wheref. by a well known property, GE is \perp to AC , and consequently \parallel to PO . Theref. the \triangle s EGI , ROP are equi-angular, and

$$GI : GE :: RP : RO, \text{ also } CG : GE :: CR : RO; \text{ wherefore,}$$

$$GI : CG :: RP : CR. \text{ Therefore } I, P, C, \text{ are in a straight line.}$$

If O' be the centre of a circle touching the base and the continuation of the other two sides in X' , R' , and Q' , then if $O'X'$ be drawn to meet IC produced in P' ; the points R', P', Q' , will be in the same straight line.

The same, answered by Mr. Swale.

Fig. 520, Pl. 28. Let ACB be a plane \triangle , bisect the base AB at I by the $\perp IX$; also bisect the vertical $\angle ACB$ by the line CE , meeting IE in E : demit upon the sides CA, CB , the \perp s EG, EH , and join GH . Then, I say GH will pass through I :—For

I:—For, let GH meet EC in D, then since $EC = EC$, $\angle ECG = ECH$, and $\angle EGC = EHC$, the \triangle s EGC, EHC are equal in all respects, theref. $CG = CH$, and theref. the \triangle GCH is an isosceles one. But CD or CE bisects the vertical \angle GCH of the isosceles \triangle GCR, theref. GD is \perp to CE. Hence, by Harrison's Propositions in the Repository, GD passes through I, the middle of AB.

Now, take any other point O in EC, and demit upon CA, CB the \perp s OR, OQ; draw OP \parallel to EI, meeting CI in P, and join RQ. Then, I say, RQ will pass through P:—For, let RQ, meet OC in D', and through P, \parallel to AB draw ab, meeting CA, CB at a and b; then since $AI = IB$, and $ab \parallel$ to AB, the base ab will also be bisected by the line CI, that is, $aP = Pb$. Now, by reasoning as above, it appears that QD' is \perp to CO, and also passes through P the middle of ab, therefore RQ passes through P.

Whence, taking the point O, the centre of the inscribed circle, the demonstration follows from the foregoing general one.

COR. Produce PO to meet AB at T, produce also IE to H', making $EH' = EG = EH$: the points C, T, H' are in a right line.

XXIV. QUESTION 234, answered by Mr. I. H. Swale.

Fig. 521, Pl. 28. Produce EG, KH, to meet at Q, and join QA, QB, QC; let AL, BQ, CQ meet BC, CF, BK at I, S, R, respectively: the lines BK, CF intersecting at P.

Now, $QG = AH = AC$, $GA = AB$, and the $\angle AGQ = BAC$, theref. the \triangle s ABC, AGQ are equal in all respects, and theref. the $\angle GQA = BCA = BAI$, that is, because GQ, BA are parallel, QAI is a continued right line, that is, IA produced passes through Q; theref. QI is \perp to BC.

Again, since, $AC = CK$, $AQ = BC$, $\angle BCA = QAH$, and ACK, CAH right angles, it follows that the \triangle s BCK, CAQ, are also equal in all respects, theref. $\angle CBR = CQI$, that is, CRB is a right angle; theref. BR is \perp to QC.

In like manner it may be shewn that CS is \perp to QB. Hence, QI, BR, CS, are respectively \perp to the sides BC, CQ, BQ of the \triangle CBQ. But the \perp s from the respective \triangle s of any plane Δ , upon the opposite sides, are known to meet in the same point. That is, AL, BK, CF, intersect each other at the same point P.

The same, answered by Meritotes Minor.

Instead of AL being drawn \perp to BC , let it pass through the intersection P of BK , CF . Then AD appears to be \perp to CS , for $\angle CFB = \angle BAD$, *Emerson's Geom.* 6. II. and $\angle BCF = \angle ACS$ *Ibid.* 2. I; consequently $\angle AS'C = \angle BCF =$ a right angle. In like manner it may be shewn that AE is \perp to BK . But, *ibid.* 34, II. The three \perp s drawn from A , E , D , upon the opposite sides, all meet in one point M ; theref. CP , BP being \perp and parallel to EM , DM , respectively, they must also meet AL in one point P , when AL is \perp to DE or BC .

The same, answered by Mr. Lowry.

The lines mentioned in the question do meet in the same point, as will be manifest from what follows. Let the lines CF , BK , meet in P , and through P draw APL to meet DE at L . Then it must be proved that AL is \perp to DE . Draw AD , AE meeting BK in R' and S' , and CF in V and Q' , and join the points R' , V and $S'Q'$. It is evident from the proposition mentioned in the question that the \angle s BCS' , BDS' are equal, and also the \angle s CEQ' , CBO' , theref. the \angle s DSC , $BQ'E$ are right angles, and the points C , E , D , B , S' , Q' , are in the circumf. of a circle, and conseq. the \angle s $Q'S'V$, $Q'BC$, are equal. Again, because of the right angles at S' and Q' , the points R' , S' , Q' , V are in the circumf. of a circle, wheref. the $\angle K'R'V$ is \perp to the $\angle Q'S'N$, that is \perp to the $\angle Q'BC$; theref. $R'V$ is \parallel to BC . Let AL meet $R'V$ at N , then the \angle s $R'VS'$, $KQ'S$, and PAS' are equal (for the points S' , P , Q' , A are in the circumf. of a circle), theref. the \triangle s ASP , PNV are equiangular, and ASP is a right angle, theref. PNV is also a right angle, and consequently AN is \perp to $R'N$, and AL to DE .

Messrs. Hill, Marrat, May, and Peacock favoured us with neat demonstrations of this proposition.

XXV. QUESTION 235, answered by Mr. Coniffre.

When the given point is within the circle.

ANALYSIS. Fig. 522, Pl. 28. Let DPE be the required line, passing through the given point P and cutting the periphery of the circle in the points D and E . Through P draw the diameter AB , upon which let fall the perpendiculars Dm , Eh ; and from the centre C draw $CQ \perp$ to DE . Draw Es , $QR \parallel$ to AB , meeting

meeting Dm in e and R respectively: also draw $Cr \parallel$ to Dm to meet QR in r .

CASE I. When $Dm + En =$ a given magnitude.

The Δ s PCQ , and EDe are similar, theref. $CP:CQ::DE:De$, whence (Euc. 16. VI.) $CQ \times DE = CP \times De$; now CP is given, and $De = Dm + En$, is given by the question; from whence, therefore, CQ may be found. Moreover CQP being a right angle, the locus of Q will be a circle whose diameter CP is given:—if theref. this circle be described and CQ determined as above, this case of the problem may be easily constructed.

CASE II. When $Dm - En$ is a given magnitude.

The chord DE is bisected in Q (Euc. 3. III.); wheref. because of the parallels Ee , QR , De is bisected in R , and theref. $Rm = Cr =$ half the diff. of Dm and me , or of Dm and En . Whence this case may be readily constructed.

CASE III. When the rectangle $Dm \times En =$ a given magnitude.

Draw $PT \perp$ to AB , to meet the periphery of the circle in T . The Δ s PDm , and PEn are similar, theref.

$PD:PE::PD^2:PD \times PE = PT^2::Dm:En::Dm^2:Dm \times En$; from whence, by alternation, $PD^2:Dm^2::PT^2:Dm \times En$.

The Δ s PDm and PCQ are also similar, wherefore

$PD^2:Dm^2::PC^2:CQ^2$, conseq. $PT^2:Dm \times En :: PC^2:CQ^2$, now PT and PC are each given, and the rectangle $Dm \times En$ is given by the question; from whence, therefore, CQ becomes known and a construction therefore quite obvious.

Or, a construction to the third case of this part of the problem will be very obvious from what follows.

Draw $TV \perp$ to DE ; then, by the sim. Δ s CQP , and PVT , $PT^2:PV^2::PC^2:CQ^2$, whence, and from what is done before, it appears that $PV^2 = Dm \times En$, which is a curious theorem.

When the given point is without the circle. Fig. 523, Pl. 28.

CASE I. When $Dm + En =$ a given magnitude.

The chord DE is bisected in Q (Euc. 3. III.), wheref. because of the parallels Ee , QR , $DR = Re$, whence $2mR = 2Cr = Dm + em = Dm + En =$ a given magnitude by the question. And because CQP is a right angle, the locus of Q will be a circle whose diameter is CP :—theref. let this circle be described, and the following construction offers itself.

Erect $Cr \perp$ to AB and = to half the given sum of Dm and En ; through r draw $Q \parallel$ to AB , to cut the periphery of the circle whose diameter is CP in Q ; through P and Q draw PED , cutting

cutting the given circle in E and D, and the thing is done as is evident from the analysis.

CASE II. When $Dm - En =$ a given magnitude.

It is evident that $Dm - En = Dm - me = De$ a given magnitude by the question. Moreover the Δ s PCQ, and EDe are similar, theref. $CP : CQ :: DE : De$, whence (Euc. 16. VI.) $CQ \times DE = CP \times De$; but CP is given, and De is given by the question, theref. CQ may be determined from hence, and this case of the question thereby readily constructed.

CASE III. When the rectangle $Dm \times En =$ a given magnitude.

Draw the tangent PT:—Then by the parallels Dm, En , $DP : PE :: DP \times PE = PT^* : Dm \cdot En : Dm \times En$; from whence by alternation $DP^* : Dm^* :: PT^* : Dm \times En$.

The Δ s PDm, and PCQ are similar, therefore $DP^* : Dm^* :: PC^* : CQ$, consequently $PT^* : Dm \times En :: PC^* : CQ^*$; but PT and PC are each given, and the rectangle $Dm \times En$ is given by the question; whence CQ becomes known and the construction from thence manifest.

Or, a construction of the third case of this part of the problem may be had from what follows.

On PC take $PT' = PT$, and upon PT' as a diameter describe a circle cutting the line PD in V, and join TV. The Δ s PCQ, and $PT'V$ are similar, theref. $PT'^* = PT^* : T'V^* :: PC^* : CQ^*$, wheref. from what is done above, it appears that $T'V^* = Dm \times En$, which is another curious theorem.

The same, answered by Mr. Lowry.

When the given point is without the circle. Fig. 524, Pl. 28.

Let P be the given point, BEFA the given circle, and suppose the chord PEF to be drawn as required, namely, so that demitting on the diameter PBA the \perp s EH, FK, their sum difference, or rectangle may be given.

1. When the sum is given. Bisect EF at G, and on AB drop the \perp GI; then GI is evidently $=$ to half the sum of EH, FK, theref. GI is given. Now, if O be the centre of the circle, OG being joined will be \perp to EF; theref. the locus of the point G will be a semicircle described on PO; consequently if PQ be drawn \perp to PA and $=$ to half the given sum, a parallel to PA, drawn from Q, will intersect the semicircle at G, through which if PG be drawn it will be done.

If E' be the point where the circles intersect, PE' will be a tangent to the circle BEF at E'; theref. it is evident that the given sum must not be greater than twice the \perp drawn from E' to AB.

s. Wh.

2. When the difference is given. In AB find the point P' so that $BP' : AP' :: PB : PA$; then it follows from, Lawson's 7th Prop. (demonstrated in the Repository) that if any line whatever as PEF be drawn to meet the circle at E and F , and FP' be drawn to meet the circle again at S , the line joining ES will be \perp to AB ; conseq. SH will be $=$ to EH , and theref. the difference between FK and SH will be given. Bisect SF at V , and on AB demit the $\perp VL$, then it is evident that VL is $=$ to half the diff. of FK and SH , and is therefore given. Now, because OV is \perp to SF , the locus of the point V is a semicircle described on OP' . Theref. if in this semicircle VL be applied perpendicularly to $P'Q$, and of the given length, the point V will be determined, and the remaining part of the construction manifest.

The difference will evidently be a maximum when $P'O$ is bisected at L in which case it is $= P'Q$. Or if $P'E'$ be drawn, and OE' joined; by Lawson's 15th Prop. $P'B'$ is \perp to AB ; theref. $OB' = OE' = OP' \times OP$, and $OG' = PO \times OI$, (Euc. Cor. 8. VI.) ; whereof $OE' : OG' :: 2 : 1$.

3. When the rectangle is given.

By similar triangles $PE : PF :: EH : FK$, and therefore, $PE \times PF = PE' \times PF' = PO \times PP' : PF' :: EH \times FK : FK' = PO \times PP' : PO' : OG' = PO \times OI$, therefore by equality, $PO \times PP' : PO' :: EH \times FK : PO \times OI$, or $PP' \times OI = EH \times FK =$ a given space : but PP' is given, theref. OI is given, and the method of construction is evident.

The rectangle will manifestly be a maximum when OI is so ; that is, when it be becomes $=$ to OP' , or when EH and FK coincide.

When the given point is within the circle.

If P' be the given point within the circle, and a point P be found without so that $BP : AP :: P'B : P'A$, the constructions and determinations will be the very same as the preceding.

The same, answered by Mr. I. H. Swale.

I. When the sum of the perpendiculars is given and the given point within the circle Fig. 524.

Let P' be the given point, draw the diameter BPA , and $P'E'$ \perp thereto, meeting the circle at E' , and let the tangent $E'P$ meet $P'B$ produced at P . Perpendicular to BA , in a semicircle on OP , apply IG $=$ half the given sum ; draw PG meeting the circle at E and F , and through E , P' , or E, P' , draw the required chord $EP'B'$, or $FP'S$.

Draw ES , FB' , meeting BA in H , K , and join OG : then since ES , FB' are \perp to AB , we shall have $HE = HS$, and KB

KB = CF, or HS + BK = HE + KF =, because OG is \perp to EF, to \angle IG = the given sum by construction.

When the given point is without the circle, Mr. Swale's Construction is the same as Mr. Lowry's given above.

II. When the difference of the perpendiculars is given and the given point without the circle. Fig. 524.

Draw to the circle, the tangent PE', and, demit upon AB, the diameter drawn through, the \perp E'P. Perpendicular to BA, in a semicircle described on P'O, apply LV = half the given diff. and join P'V which produce to the circle at F, and through P, F, draw the required line meeting the circle at E and F.

Produce FP' to the circle at S and join SE, meeting AB in H. Demit upon AB the \perp FK, also join OV. Then since ES will cut AB perpendicularly at H, we shall have EH = HS, and FK — EH = FK — HS. Now draw through V, parallel to AB, the line RVN, meeting EH, FK in R, N. The points P', V, O, are in a semicircle, theref. OV is \perp to SF, that is, SV = VF; theref. by parallels FN = SR, FK = FN + NK = SR + NK = SR + RH = SH + $\frac{1}{2}$ HR = SH + $\frac{1}{2}$ LV = EH + $\frac{1}{2}$ LV, and FK — EH = EH + $\frac{1}{2}$ LV — EH = $\frac{1}{2}$ LV = the given diff. by construction.

When the point is within the circle as at P', it will be determined by the const. given above, the demon. being of course the same.

III. When the rectangle of the perpendiculars is given, and the point without the circle. Fig. 524.

Draw PBA, PE', and EP' as in the last case. Apply in the circle, \perp to AB, L'L' the side of a square = to the given magnitude and to a semicircle on P'B, apply OS' = OL'; join P'S, produce P'S' to the circle at E, and through PE draw the required line meeting the circle E and F.

Produce EP' to the circle at B', join B'F, meeting AB in K; upon AB demit the \perp EH, join OS' which produce both ways to the circle at G and H. Then, as before, from known properties B'F is \perp to AB, and FK = KB', or $\frac{1}{2}$ FK \times $\frac{1}{2}$ EH = B'F \times $\frac{1}{2}$ EH =, by sim. Δ s, to B'E' — EF': But since the points P', S', B, are in a semicircle, BS' will be \perp to EB'; or B'E' + EF = $\frac{1}{2}$ BS', and BE' — EF = $\frac{1}{2}$ ES, that is, $\frac{1}{2}$ BS' \times $\frac{1}{2}$ ES' = B'E' — EF' = B'F \times $\frac{1}{2}$ EH = $\frac{1}{2}$ FK \times $\frac{1}{2}$ EC; and FK \times EH = $\frac{1}{2}$ BS' \times S'E' =, by the circle, to G'S' \times SH': Now, by constr. OS' = OL', and by the circle OB = OA = OG = OH, or G'S' = AL', and H'S' = BL'; that is, BL' \times L'A = G'S' \times SH' = FK \times EH from above, = L'L', by the circle, = the given magnitude by construction.

When the point is within the circle, the const. will be the same as the above.

Messrs. Andrew, Thornoby, and Whalley also answered this question very ingeniously.

XXVI. QUESTION 236, answered by the proposer,
Mr. Lowry.

CONSTRUCTION. Fig. 525, Pl. 28. Let AB , BC and AC be the three straight lines given by position, and let Ca , Cb , Cd , be respectively \parallel to the lines drawn from the required point to AB , BC , and AC . Produce aC till it meets AB at D' , and take $D'a$ \equiv to the given sum; draw $Q'aQ$ \parallel to AB to meet AC , BC , produced, in S and X . Take Cb and Cd , each \equiv to Ca , and draw SbM , XdN , to meet BC and AC , in M and N respectively; draw also $MH \parallel$ to Cb , to meet AC at H , and $LN \parallel$ to Cd to meet CB at L ; join LH meeting AB , produced at R . Through H draw $HW \parallel$ to Ca , and continue it to meet LW , drawn \parallel to AB , cut W . Then, by Prob. 2nd, of the Determinate Section, by Snellius, at HR at P , so that the rectangle $HP \cdot PL$, may have to the rectangle contained by PR and the given line, the given ratio of $HW \cdot HL$ to $LN \cdot HM$; then P is the point required.

DEMONSTRATION. From P draw PDG , PE , and $PF \parallel$ to Ca , Cd , and Cb respectively, and let the line drawn through the points I , L , meet GP at O , also draw $LK \parallel$ to Ca .

Then, because of the parallels, it is evident, since Ca ($\equiv Cb$) is $\equiv Cd$, that LK is \equiv to LN , and $HI = HM$. And by sim. Δ s,

$IL : IO : : LK : QG$ ($\because LH : HP :: LN : PE$),
but LK is $\equiv LN$, therefore QG is $\equiv PE$. Moreover,
 $IL : OL : : HL : LP :: HM : PF :: HI : PO$,

but HI is $\equiv HM$, therefore PO is $\equiv PF$. Consequently,
 $PE + PF + PD = D'a$, that is, \equiv the given sum, by constr.

Again, let Q be the given line. Then by sim. Δ s,

$HP : PE :: LH : LN$, and $PL : PF :: LH : HM$, and compounding

$HP \cdot PL : PE \cdot PF :: LH \cdot LN : HM$. But, by construction,

$HP \cdot PL : PR \cdot Q :: HW \cdot HL : LN \cdot HM$, therefore, *ex equo perturbate*,

$PE \cdot PF : PR \cdot Q :: HW \cdot HL : LI :: HW : HL$; and by sim. Δ s,

$HW : LH :: DP : PR :: DP \cdot Q : PR \cdot Q$; therefore

$PE \cdot PF : PR \cdot Q :: DP \cdot Q : PR \cdot Q$; and theref. $PE \cdot PF = DP \cdot Q$.

The same, answered by Mr. Gunliffe.

Lemma. To find a point, in one of three right lines, given by position, whence if two right lines be drawn in given angles to the other two, the sum of the two lines so drawn may be of a given length.

Con-

CONSTRUCTION. Fig. 526, Pl. 28, Let AB , AC and BC be the three lines given by position: Take AM of the given length and making with AB the given angle MAB ; through M draw Mb parallel to AB , meeting BC and AC in b and a respectively. Draw AV to meet CB in V , making the $\angle AVC$ equal to that made with the line BC : upon AV take $Am = AM$, and draw am cutting BC in G ; through G draw GD parallel to AV meeting AC in D , and the thing is done.

DEMONSTRATION. Through D , draw $gL \parallel$ to AM , terminating in Ma and AB in g and L . By reason of the parallels Dg , AM ; DG , Am ; $aA : AM = Am : : aD : Dg = DG$; theref. $DL + DG = DL + Dg = Lg =$ the given length by constr. and Euc. 34. I. Moreover, $\angle DLB = MAB$, and $\angle DGC = AVC$, the given angles by construction and Euc. 28. I.

Q. E. D.

The above being premised, the solution of the problem may be as follows;

Fig. 527, Pl. 28. Let AB , AC and BC be the three lines given by position. In one of them as AC , by the preceding Lemma, find the point D , such, that drawing DG to BC , and DL to AB in the given angles of the straight lines to be drawn to these lines, $DL + DG$ may be equal to the given sum of the three lines. In like manner, in BC find the point E , from whence drawing EH to AC , and EK to AB in the respective given angles of the lines to be drawn to these lines, $EH + EK$ may also be equal to the given sum of the three lines. Through D and E draw the right line DEF to meet AB in F , and this line DEF is the *locus* of the required point P .

For, upon LD and KE take Lg and Kh , each equal to the given sum of the three lines, and draw Dh and gh . From any point P in DF draw the lines PQ , PR , PS respectively parallel to DG , EH , DL to meet the lines BC , AC , AB in Q , R and S ; also produce SP to meet Dh and gh in r and q respectively. Because of the parallels PR , EH ; PR , Eh ;

$DE : DP :: EH = Eh : PR = Pr$. Also

$ED : EP :: hD : hr :: DG = Dg : PQ = rq$; wherefore

$PS + PR + PQ = PS + Pr + rq = Sq = Lg$ the given sum by construction.

Now, suppose P to be the point required, upon DF take Dd equal to the given line, the rectangle under which and PS , shall be equal to the rectangle under PR and PQ , that is $Dd \times PS = PR \times PQ$, and through d draw de parallel to AB meeting DL in e . Then by the sim. Δ s Dde and PFS ,

$Dd : De :: FP : PS$, whence $Dd \times PS = De \times FP$.

Also by reason of the parallels DG , PQ ; EH , PR ,

$DE : DG :: EP : PQ$, and $DE : EH :: DP : PR$, whence

F_2

DE

$DE : EH \times DG :: DP \times EP : PR \times PQ = Dd \times PS = De$
 $\times FP$, a given ratio, because DE , EH and DG are all given as also
 De ; from whence it is plain that this part of the problem belongs
to the determinate section, by means of which the point P may
be found.

Mr. Swale answered it.

XXVII. QUESTION 237, answered by Mr. Cunliffe.

Put $P = 1000$, and let n denote the time in quarters, in which
the debt will be liquidated, in the manner stated in the problem;
also let r be taken such that $r^4 = 1.05$, whence $r = 1.012272$,
which is the amount of £1. at the end of the first quarter at the
given rate. Then by the question, and the principles of compound
interest, $\frac{1}{r}$ will express the present worth of the first quarterly pay-
ment; $\frac{2}{r^2}$ that of the second quarterly payment; $\frac{3}{r^3}$ that of the
third quarterly payment; and, generally, $\frac{n}{r^n}$ will express the
present worth of the n th quarterly payment: wherefore

$$P = \frac{1}{r} + \frac{2}{r^2} + \frac{3}{r^3} + \frac{4}{r^4} + \&c. \dots \frac{n}{r^n}.$$

The sum of n terms of this series may be obtained as follows.

By division $\frac{x}{1-x} = x + x^2 + x^3 + x^4 + \&c.$ taking the flux-
ions and dividing by

$\frac{x}{x}$ gives $\frac{x}{(1-x)^2} = x + 2x^2 + 3x^3 + 4x^4 + \&c.$ Again

by division $\frac{x^{n+1}}{1-x} = x^{n+1} + x^{n+2} + x^{n+3} + \&c.$ taking the
fluxions and dividing by $\frac{x}{x}$ as before gives

$$\frac{(n+1)x^{n+1} - nx^{n+2}}{(1-x)^2} = (n+1)x^{n+1} + (n+2)x^{n+2} + (n+3)x^{n+3} + \&c.$$

Now

Now this latter series is evidently a continuation of the former after the n leading terms; therefore taking the difference of the expressions there will be had

$$\frac{x + nx^{n+2} - (n+1)x^{n+1}}{(1-x)^2} = x + 2x^2 + 3x^3 + 4x^4 + \dots + nx^n.$$

Write $\frac{1}{r}$ in the place of x , and the last expression will become

$$\frac{\frac{1}{r} + \frac{n}{r^{n+2}} \frac{n+1}{r^{n+1}}}{(1-\frac{1}{r})^2} = \frac{r^{n+1} + n - (n+1)r}{r^{n+2} \times (1-\frac{1}{r})^2} = \frac{r^{n+1} + n - (n+1)r}{r^n \times (r-1)^2}$$

$$= \frac{1}{r} + \frac{2}{r^2} + \frac{3}{r^3} + \frac{4}{r^4} + \dots + \frac{n}{r^n}; \text{ Conseq. } \frac{r^{n+1} + n - (n+1)r}{r^n \times (r-1)^2} = P;$$

whence by reduction $r^n = \frac{(n+1)r-n}{r-P \times (r-1)^2}$; and taking the logarithms;

$$n \times \log.(r) = \log. \left(\frac{(n+1)r-n}{r-P \times (r-1)^2} \right) \text{ or } n = \log. \left(\frac{(n+1)r-n}{r-P \times (r-1)^2} \right) \div \log.(r) = \log. \left(\frac{(n+1)r-n}{86167} \right) \div 0052972; \text{ this formula is very convenient}$$

for finding the value of n by the rule of double position, by means of a few trials of which, there will be had $n = 55.228$ quarters = 13.807 years, which is very near the truth.

The same, answered by Mr. David Davis.

Put $P = 1000$, $r = \sqrt[4]{1.05}$, the amount of 1*£.* at the end of the first quarter, and t = the number of quarters required.

Then by the principles of compound interest and annuities, and the nature of the question,

$pr^t = r^t - 1 + 2r^{t-2} + 3r^{t-3} + 4r^{t-4} + \text{ &c. to } t \text{ terms};$ therefore

$$p = r^{-1} + 2r^{-2} + 3r^{-3} + 4r^{-4} + \text{ &c. to } t \text{ terms},$$

$$= \frac{1}{r} + \frac{2}{r^2} + \frac{3}{r^3} + \frac{4}{r^4} + \text{ &c. to } t \text{ terms},$$

$= \frac{r^{t+1} - (t+1)r + t}{r^t \times (r-1)^2}$. See Clarke's Translation of

Lorgna's Series, Form 190, or Dodson's Mathematical Repository,

Page 65, vol. ii. Whence $t = \log. \left(\frac{(t+1)r-t}{r-p(r-1)^2} \right) + \log. (r)$,

and $t = 55.228$ the number of quarters required.

And thus nearly was the answer given by Mérones Minor, and Mr. Marrat of Boston.

To XXVIII. QUESTION 238, we have received no answer.

XXIX. QUESTION 239, answered by Mr. Lowry, the proposer,

ANALYSIS. Join BP (fig. 528, pl. 28.) and draw PG to make the $\angle BPG =$ the given one; take PG = PG and draw GI to make the $\angle PGI = BPE$: then, it is evident that the Δ s GPI, BPE, are every way equal, theref. GI is = BE. Take PH : PG :: M : N, and make the rectangle N \times P = the given one, and draw HK \parallel to GI meeting AC at L: then, KH : GI :: M : N, wheref. N \times KH = M \times GI = M \times BE, and N \times KH \pm N \times CF = N \times P, or KH \pm CF = P = a given line.

Moreover LA and LC are given lines, theref. KL \pm FL is given, and PF may be drawn as in my solution to Question 220. It may also be drawn differently as follows: Through the points K, L, F (fig. 529, pl. 28.) describe a circle and draw the diameter TID \perp to KF, also draw DR and TS \perp to LF, and RQ \perp to the line joining the points D, L; draw also SI \parallel to DL. Then it is well known that LR is = to half the sum, and LS = to half the difference of KL, LF, and that RQ and SI meet at I, the middle of KF; we have theref. the following simple Construction.

1. When the sum is given. Take LR = half that sum, and draw LD to bisect the $\angle KLF$; on LD drop the \perp RQ, and make RD \perp to LR; then a semicircle described on the diameter PD will intersect RQ at I.

2. When the difference is given take LS = half the given difference, draw ST \perp to LS, meeting LT, drawn \perp to LD, at T, and draw SI \parallel to LD; then a semicircle described on the diameter PT will intersect SI at I.

The

The same, answered by Mr. James Cunliffe.

CASE I. When the sum of the rectangles $BD \times M$ and $CE \times N$ is equal to a given space. Fig. 530, Pl. 28.

Join PB , and draw PF meeting AC in F , and making the $\angle BPF$ \equiv to the given \angle . In PF take $Pb = PB$ and divide Pb in R , so that $N : M :: Pb : PR$. Also take RS of such a length that the rectangle $RS \times N$, may be \equiv to the given space, and the $\angle bRS = PBA$. Then, by *Halley's Apollon. de Sectione Rationis*, from the given point P draw the right line PEG , cutting AC in E and RS in G , so that $CE = GS$; also draw PD to AB , so that the $\angle EPD = FPB$ and the thing is done.

For, draw $bd \parallel RS$, meeting PE in d . By the const. $\angle PRS = PBD$, Euc. 27. I. $\angle Pbd$; also $bPB = dPD$, and taking away the common $\angle dPB$, there will remain $\angle bPd = BPD$: whence, by Euc. 26. I. the Δ s bPd and BPD are equal in every respect; wherefore, by reason of the parallels bd , RG ; $N : M :: Pb : PR :: bd = BD : RG$, theref. by Euc. 16, VI. $RG \times N = BD \times M$. By the constr. $RG + GS = RG + CE = RS$; wherefore $RG \times N + CE \times N = BD \times M + CE \times N = RS \times N$, the given space, by the construction.

CASE II. When the difference of the rectangles $BD \times M$ and $CE \times N$ is equal to a given space.

Take RS' on the contrary side of Pb , and of such a length that the rectangle $KS' \times N$ may be equal to the given space. Then, by *Halley's Apollon. De Sectione Rationis*, draw the right line PEG cutting AC and RS' in G so that $CE = GS'$; also draw PD to AB so that $\angle EPD = BPF$, and the thing is done.

For, by what is done in the preceding case $BD \times M = CE \times N$, and by constr. $GS' - GR = CE - GR = RS'$; wheref. $CE \times N - GR \times N = CE \times N - BD \times M = RS' \times N$ the given space by the construction.

The same, answered by Mr. I. H. Swale.

CASE I. When the sum of the rectangles is given.

Fig. 531, Pl. 28. The lines PD , PE being supposed drawn as required, join BC : Take $BF = M$, and $CG = N$, join FC , GB , and draw, to BC , the lines DH , EI , making $\angle BDH = BCF$, and $\angle CEI = CBG$, and produce DH , EI to meet at Q . The points D , C , F , H , are in a circle, and so are the points E , B , G , I , theref. $BF \times BD = BC \times BH$, and $CG \times CE = CB \times CI$. Theref. the sum of the rectangles $BD \times BF$, and $CE \times CG$, that is, the sum of the rectangles $BD \times M$ and $CE \times N$ is \equiv to the sum of the rectangles $BC \times BH$, and $BC \times CI$,

CI, that is, = to the rectangle under BC and the sum of BH, CI, = to a given rectangle: But BC is a given line, therefore the sum of BH, CI is given; theref. HI is a given line. Now, through Q, draw RS \parallel to BC, meeting AB, AC in R and S; draw also RK, SN \parallel to QE, QD, meeting AC, AB, in K and N.

Now, $\angle QHI = BFC$, and $QIH = CGB$, being given, the $\triangle HQI$ is given in species, and, being described upon a given base HI, it is therefore given in magnitude. Theref. since $HQ : BR = DH : DB$, is a given ratio, BR is given, and of course the line RS is given in position.

Moreover, by reason of the parallels, $RD : DN = QR : QS = EK : ES$, *et componendo*, $RN : SK = RD : EK$, a given ratio; since the points R, S, are given from above, and the lines RK, SN, making given angles with RS, are given by position, or the lines RN, SK, and their ratio therefore given.

Now the lines AR, AK, are given by position, R and K are given points therein, and P is a given point without them; we have only therefore to draw two lines PD, PE, to contain a given \angle , meeting AR, AK, in D and E, and making $DR : EK$ a given ratio, which has been done at question 152.

CASE II. When the difference of the rectangles is given.

Fig. 532, Pl. 28. Having drawn lines as in the preceding case, it will appear, that, the rectangle under BC and the diff. of BH, CI is given, and because BC is a given line, the diff. of BH, CI will be given. Biseet BC in M, make $IW = HM$, and draw MV, WV parallel to DQ, EQ, meeting each other at V, and the lines AB, AC in L and K; through V draw RS \parallel to BC, meeting AB, AC in R, S, and DQ, EQ in U and T..... Then, the diff. of BH, CI will be = to the diff. of MI, MH, that is equal to MW, a given line; theref. the point W is given; conseq. the $\triangle MVW$ is given in species, magnitude, and position, that is, the point V is given; therefore the line RS passes through a given point and is \parallel to a given line; consequently the lines KS, LN are given in length, N being the point where SN, drawn \parallel to VL, meets AB. Whence, by parallels, $DL : LN = VU (= VT) : VS = EK : KS$; *et alternando*, $LN : SK = DL : EK =$ given ratio: But AL, AK, are lines given by position; L, K, given points therein, and P a given point without them, DPE a given \angle , and $LD : KE$ a given ratio. And therefore this case is the same as the preceding one.

Remark. When PD, PE, are to be drawn including a given angle, and making the sum or diff. of BD, CE = to a given line, the same conclusions are still derived.

For,

For, accordingly as the sum or diff is given, set off, above or below C (fig. to Case I.) CT or CV equal thereto. Then in the former case we shall have $BD = TE$, and in the latter $BD = VE$: theref. drawing, by the solutions to Question 152, the lines PD, PE, making $DPE =$ the given \angle , and $BD : TE$, or $BD : VE$ in the ratio of equality, and it will be done. The points B, and T or V being evidently given ones.

XXX. *Or, PRIZE QUESTION 240, answered by Mr. Swale.*

Let ABCD (fig. 533, pl. 28.) be the circle given in magnitude and position, and P, Q, and R the given points.

Suppose the required trapezium inscribed in the given circle, and that the fides CA, BD; AD, CB, when produced intersect each other at the points P and Q, also that one of the diagonals, as CD, passes the given point R.

Now, join PQ, and it will be given in length and position. From A and B draw AK, BL, parallel to PQ meeting the circle at K and L; then by parallels, the arches AL, BK, are equal. Join AL, and produce LA to meet PQ at G; then, again, by reason of the parallels, the $\angle AGP = ALB = ACB$, by the circle; therefore the $\angle QGA =$ supp. of the $\angle QCA$, or the points Q, C, A, G, are in a circle; therefore, $PQ \times PG = PC \times PA$. Again the $\angle PGA = PDA$, therefore the points P, G, D, A, are in a circle; theref. $GQ \times QP = DQ \times AQ = BQ \times QC$; and therefore $PQ \times PG + PQ \times QG = PQ^2 = PC \times PA + QB \times BC =$ the sum of the squares of the tangents drawn to the circle from P and Q*. Wherefore it appears that the given points must be so situated, with respect to the circle, that the square of PQ must be equal to the sum of the squares of the tangents from P and Q, so that the problem *cannot* be constructed *generally* for any situation of the points, but only for the particular one specified above.

Let O be the centre of the given circle, draw GO meeting the circle in I and H, and CD in S, also let CG when drawn meet the circle in F; then, because $PQ \times PG = PC \times PA$, and $GQ \times QP = BQ \times QC$, it is evident, from Mr. Harris's demonstration to *Lawson's* 33rd proposition, that GO is perpendicular to PQ, AK and BL, therefore the arch IK = the arch LS, and the points G, K, B, are therefore in a straight line. Again, because OG is perpendicular to PQ, by *Lawson's* 11th proposition $JG \times GH + GP^2 = AP \times PC$, that is, $= GP \times PQ$; take

GP^2

GP from each, and $IG \times GH = PG \times GQ$; therefore, by *Lawson's* 28th proposition $IG : GH :: SI : SH$; consequently S is a given point: Hence the following simple

CONSTRUCTION. Join the first two given points P, Q; and upon PQ, from the centre O of the given circle, demit the perpendicular OG, meeting the circle in H and I; make $HS : SI = HG : GI$, and join the third given point R with the point S; let RS meet the circle in C and D, join PD, QD, meeting the circle again at B and A, and join CA, CB: so shall CA, CB, produced pass through the points P and Q, and ABCD will be the trapezium required, as is evident enough from the analysis.

The truth of question 10 in the British Magazine is evident from the expression marked *

The following **THEOREM** is also true, and may be of use in the construction of Problems.

THEOREM. Let S be the intersection of the diagonals of a trapezium, inscribed in a circle, whose centre is O, join OS, and make OG equal to a third proportional to OS and the radius of the circle: Then the line joining the points of intersection of the opposite sides of the trapezium produced, will pass through the point G and be perpendicular to GO.

The same, answered by Mr. Richard Nicholson, Liverpool.

ANALYSIS. Suppose the thing done, ABCD (fig. 540, pl. 28.) the trapezium required, and E, F and P the given points. Draw EF, and CH parallel thereto meeting the circle at H, draw also HAG meeting EF in G, and join GC. Now (Euc. III. 21, and I. 29.) the $\angle ABC = AHC = HGE$; theref. a circle will pass through the points A, B, F and G: wheref. (Euc. III. 36.) the rect. $EF \cdot EG = EB \cdot EA = EC \cdot ED$, a given magnitude; theref. G is a given point, and a circle will pass through the points G, F, C and D; therefore the $\angle HCG = FGC = FDC = CHG$, wheref. $HG = CG$; Draw KI perpendicular to HC, and GI perpendicular to HC also, and $HI = IC$, theref. GK is one continued straight line, that is, the line GL, drawn through the centre K, will be perpendicular to HC or EF, and therefore the point O becomes known by *Lawson's* 7th Proposition: hence the position of the diagonal AC is given.

CONSTRUCTION. From the centre K draw KG perpendicular to EF, draw any line GH to meet the circle in A and H, and HC perpendicular to KG to meet the circle in C and join A, C. Through the point of intersection of AC, GK, and the given point draw the diagonal AC, compleat the trapezium, which will be inscribed in the given circle when the points are so situated

as

as to render the problem possible*. For the $\angle EGA = FGC$, and $EAG = GFC$; therefore $EG : GA :: GC : GF$ or $EG \cdot GF = GC \cdot GA = GL \cdot GT$; and GL perpendicular to EF , therefore the points A, C, D , and B , are in the circle by Prop. 33, 34, I. *Stewart's Propositiones Geometricæ*.

The same, answered by Mr. James Cunliffe.

Fig. 535, Pl. 28. ANALYSIS. Let $ABCD$ be a trapezium inscribed in a circle, the sides BA, CD being produced to meet in the point E ; and the sides AD, BC being produced to meet in the point F . . . Draw the tangents ET, FM , and to the centre O draw EO, FO, TO, MO ; also draw Dn to meet FE in n ; making the $\angle EnD = DAB$, and join On .

Then the $\angle EnD + DAE = DAB + DAE = 2$ right angles; whence the points E, A, D, n , lie in the circumference of the same circle, per Euc. 22, III. Again, since, by construction, the $\angle EnD = DAB$, the supplements of these angles must be equal, viz. $\angle FnD = DCB$, consq. the points F, C, D, n , lie in the circumference of the same circle; wherefore, per Euc. 36, III, $Fn \times FE = FD \times FA = FM^2$, and $En \times FE = ED \times EC = ET^2$; and, by addition, $Fn \times FE + En \times FE = FE^2 = FM^2 + ET^2$. From whence it appears that the points E and F , must always have such a situation with respect to the circle, that the square of the distance between them may be equal to the sum of the squares of two tangents from them to the circle.

The \angle s ETO , and FMO are right \angle s, per Euc. 18, III; therefore $FO^2 - OM^2 = FO^2 - OT^2 = FM^2 = Fn \times FE$, and $EO^2 - OT^2 = ET^2 = En \times FE$ and theref. $FO^2 - EO^2 = Fn \times FE - En \times FE = FE \times (Fn - En)$. Therefore On is perpendicular to FE , as appears from prop. 24, B. II, *Emerson's Geometry*.

Draw $MR \perp$ to FO and join ER ; the \triangle s FRM and FMO are right angled and similar, theref. $FR : FM :: FM : FO$, whence $FR \times FO = FM^2$; and it has been shewn that $Fn \times FE = FM^2$; conseq. $FR \times FO = Fn \times FE$, wheref. per Euc. 36, III, the points E, n, R, O , are in the circumference of a circle, and theref. per Euc. 21, III, $\angle ERO = EnO =$ a right angle; wheref. ERM is a straight line and cuts FO at right angles in R . And in the same manner it may be shewn that FT cuts EO at right angles in Q ; and theref. it is plain from prop. 34, B. II, *Emerson's Geometry*.

* Note. The points must be situated as mentioned in Mr. Swale's solution.

son's

son's Geom. that the lines FT , EM and On intersect in the same point L .

These things being premised the construction of the problem may be as follows.

Let E and F be the two given points in which the opposite sides of the trapezium are to intersect, so situated with respect to the given circle TmM , as to render the question possible; also let P be the given point through which one of the diagonals of the trapezium is to pass. Having found the point I from what is suggested in the *Analysis*, through that and the given point P draw the right line DB cutting the circle in D and B ; also draw EB cutting the circle again in A , and through I draw AIC to cut the circle in C , then draw the lines BC , CD , DA , and $ABCD$ is the required trapezium.

DEMONSTRATION. Draw the lines AQ , BQ , AQ , BO , ED , FD and FC ; also draw $OS \perp$ to AB . Then from what is deduced in the *Analysis*, and Euc. 36, III, $ET^* = EA \times EB = EQ \times EQ$, wheref. the points A , B , Q , Q , lie in the circumference of the same circle; and per Euc. 20, 21, 22, III, $\angle BQA = BOA = 2BDA$ ($2IDA$), and $\angle AQE + AQB = ABO + AQB = 2$ right angles, whence $\angle AQE = ABO$: let each of these be taken from a right angle and there will remain $\angle AQT = BOS = BCA$ (BCI); and consequently $\angle BQT = AQT = BCA = BDA$ (IDA). Again from what is deduced in the *Analysis* and Euc. 36, III, $FM^* = FR \times FO = FI \times FQ = FI \times (FI + IQ) = FI^* + FI \times IQ$: and per prop. 27, B. II. *Emerson's Geom.* $FM^* = FI^* + mI \times IM$, whence, and per Euc. 35, III, $FI \times IQ = mI \times IM = AI \times IC$, wheref. the points A , Q , C , F , lie in the circumference of the same circle, and per Euc. 21, III, $\angle AQI = FCI$; whence, by addition, $\angle AQT + AQI = BCI + FCI = 2$ right angles; theref. FCB is a right line. Again since $FI \times IQ = AI \times IC = DI \times IB$, the points F , D , Q , B , lie in the circumference of the same circle, and $\angle BQI = IDF$, whence, by addition, $\angle BQT + BQI = IDA + IDF = 2$ right angles; therefore FDA is a right line. Now having demonstrated that FCB and FDA are right lines:—draw the lines BR , CR , and by proceeding as before, it may be shewn that $\angle BRM = CRM = IDC$, and $\angle BRI = IDE$, whence, by addition, $\angle BRM + BRI = IDC + IDE = 2$ right angles; theref. EDC is a right line; and therefore $ABCD$ is the required trapezium.

The following particulars naturally suggest themselves, from what is deduced in the *Analysis*, namely,

A line joining the points of contact of two tangents to the circle from either of the given points being produced will pass through the other given point.

The

The angle EOF must be less than a right angle.

For, $OT^2 = OQ \times OE = OR \times OF$; but when EOF is a right angle the points Q, R and O, coincide, and therefore the radius OT becomes = 0, or the circle degenerates to a point.

Three points being given in any position whatever, so that right lines joining them may form an acute angled triangle, a circle may be found having its centre in one of them, such that the opposite sides of a trapezium, inscribed therein, being produced will intersect in the other two, and have one of its diagonals parallel to a right line given by position.

If we imagine the shadow of the figure to be projected from a lucid point upon a plane inclined to the plane of the figure, the circle will be projected into a conic section with an inscribed trapezium, whose opposite sides produced intersect in two points so situated with respect to the conic section, that a right line joining the points of contact of two tangents to the curve from either of the points of intersection, will pass through the other. This may be gathered from what is deduced in the *Analysis*, Cor. 1. Prop. 20, B. II. of *Emerson's Nature and Property of curve lines*.

Whence it follows, that if instead of a circle, the curve had been a given conic section, the method of construction would have been in no respect different:—but then the given points must have had such a situation, that the right line joining the points of contact of two tangents from either of them would pass through the other.

The same, answered by the proposer, Mr. Lowry.

ANALYSIS. Fig. 537, Pl. 28. Suppose the thing done, ABCD the trapezium required; P, Q, the given points where the opposite sides produced intersect; and S the point through which the diagonal passes. Let O be the centre of the given circle, and draw the tangents PE, QF. Join O, E; O, F; O, P; O, Q; and draw PF to meet the circle at H, and OQ at L; and QE to meet OP at K, PF at I, and the circle at G. Join also, P, Q; P, G; and Q, H.

Then because the question requires the trapezium to be inscribed in the circle, it is evident from *Lapson's* 33rd proposition, that the position of the points P and Q, with respect to the circle, must be such that $PQ^2 = PE^2 + QF^2$. Now QF^2 is $= QO^2 - QF^2 = QO^2 - OE^2$; theref. $PQ^2 - PE^2 = QO^2 - OE^2$, and conseq. PO is perpendicular to EQ. In like manner it may be shewn that QO is perpendicular to PF; therefore PG is $= PE$, and QH $= QF$: Wherefore *Ibid.* Prop. 18. PE or $HPF = RI^2 + EIG = PI^2 +$

HIF , and QF or $GQE = QI^2 + GIE$. Whence it follows from Prop. 34, *Iid*, that if any straight line PAB be drawn meeting the circle at A and B , and AIC , PDC be drawn meeting the circle at C and D , the points D , I , B , will be in a straight line; and if any line QDA be drawn meeting the circle in A and D , and DIB , QCB be drawn meeting the circle in B and C , the points A , I , C , will be in a straight line; and because the points P and Q are so posited that a straight line will pass through the points A , D , Q , and also through the points B , C , Q , it necessarily follows, that if any trapezium whatever whose opposite sides, when produced, meet in P and Q , be inscribed in the circle, the diagonals AC , BD , will always intersect each other in the point I (*).

Now because I and S are given points, the diagonal DB will be given by position, and the *Construction* may be as follows. Draw the tangents PE , QF , and let PF , QE be drawn intersecting at I ; through I and S draw the diagonal $DISB$, join PAB , PDC , QDA and QCB , and it is done, as is manifest from the Analysis.

If only one of the points of intersection had been given, and the other had been required to fall in a line of *any order* given by position, the construction would have been very little different from the above. For it is obvious, that the straight lines FIP , EIQ , are the *loci* of the points P , Q .

That the diagonals always intersect each other in the given point I , might be proved differently as follows... For, it is manifest from Lawson's Propositions already quoted, that if from P , any two straight lines whatever, as PAB , PDC , be drawn meeting the circle in A , B ; D , C ; the *locus* of the point of intersection of AC , BC , will be the straight line EG ; and, supposing, the point P , and the lines PAB , PDC , to be removed, and from Q any two straight lines whatever, as QDA , QCB , be drawn meeting the circle at A , D ; C ; the *locus* of the point of intersection of AC , BD , will be the straight line HF . Now, when the points P , Q , are so situated that a trapezium can be inscribed in the circle, it is obvious, that the point of intersection of AC , BD , must be a point which is common to each of the *loci* EG , FH ; and consequently it must be the point I , where they intersect.

It was from this consideration that I was first led to the discovery of the beautiful PORISM exhibited in the above Analysis, (*); and at that time I was not aware that it had been thought of by any one. Since then a literary friend has favoured me with a copy of the *Opera reliqua* of Dr. ROBERT SIMSON, where I find a compleat investigation is given of this Porism.

To such of the readers of the Repository as have not had an opportunity of seeing that valuable work, an abstract of the Dr.'s investi-

investigation of this *Porism* may perhaps be acceptable. Previous to the investigation he gives the two following propositions.

PROP. I. *Being Prop. IIX. De Porismatibus.*

Fig. 538, Pl. 28. If from two points A, B, without a circle, two straight lines AC, BC, be inflected to the circumference, meeting it again in D and E, and the sum of the rectangles CA, AD; CE, BE, be equal to the square of AB joined; and M be the centre of the circle, and MK be drawn perpendicular to AB, then $BA \cdot AK = CA \cdot AD$.

And the contrary. If the sum of the rectangles CA, AD; CB, BE; be $= AB^2$, and in AB there be taken a point K, such, that $BA \cdot AK = CA \cdot AD$, then if KM be drawn to the centre it will be perpendicular to AB.

Let KM meet the circumference in N, O; then $CA \cdot AD = AK^2 + OK \cdot KN$, and in like manner $EB \cdot BC = BK^2 + OK \cdot KN$; therefore $CA \cdot AD + CB \cdot BE$ (that is, by hypothesis AB^2) $= AK^2 + BK^2 + 2OK \cdot KN$; take away $AK^2 + BK^2$, and $2AK \cdot KB = 2OK \cdot KN$; wherefore $AK \cdot KB = OK \cdot KN$; add AK^2 to each, and $BA \cdot AK = OK \cdot KN + AK^2$, that is $= CA \cdot AD$. In the same way it may be shewn that $AB \cdot BK = CB \cdot BE$.

And if the rectangle $CA \cdot AD + CB \cdot BE$ be $= AB^2$, and in AB the point K be taken making $BA \cdot AK = CA \cdot AD$; then if KM be drawn to the centre, it will be perpendicular to AB.

For, if it is not, from the centre draw MR perpendicular to AB; then by the preceding $BA \cdot AR = CA \cdot AD$, that is $= BA \cdot AK$, which is impossible; therefore MK is perpendicular to AB.

PROP. II. *Being Prop. LX. De Porismatibus.*

Fig. 539, Pl. 28. If from two points A, B, of which A is without, and B within the circle, two straight lines AC, BC, be inflected to the circumference, meeting it again in D and E; and the rectangle CA, AD be equal to the rectangle CB, BE, together with the square of AB joined; and from the centre MK be drawn perpendicular to AB, then the rectangle $BA \cdot AK = CA \cdot AD$.

And the contrary, if $CA \cdot AD$ be $= CB \cdot BE + AB^2$, and in AB there be taken the point K, such, that $BA \cdot AK = CA \cdot AD$, then if KM be drawn to the centre it will be perpendicular to AB.

Let AB meet the circumference in S, T; and because the rectangle $CA \cdot AD$, that is, $TA \cdot AS$ is $= CB \cdot BE$ or $SB \cdot BT + AB^2$, let SK^2 be added to each, then (6. II.) $AK^2 = SB \cdot BT + AB^2 + SK^2$; take away AB^2 , then $2AB \cdot BK + BK^2 = SB \cdot BT + SK^2$. Again, take away, BK^2 , and $2AB \cdot BK$ is $= 2SB \cdot BT$; therefore

$AB \cdot BK = SB \cdot BT$. Add AB^* to each, and $BA \cdot AK = SB \cdot BT + AB^*$ or $CB \cdot BE + AB^*$, that is, by hypothesis, $= CA \cdot AD$.

The second part of the proposition is proved after the same manner as the second part of the preceding.

Now, the PORISM, as enunciated by Dr. SIMSON, is as follows. Let A, B, be two given points, and to the circumference of a circle CDE given by position, let any two lines AC, BC, be inflected meeting it again in D and E, the straight line which joins the points D, E, will pass through a given point.

CASE I. When the straight line which joins the given points A, B, does not meet the circle. Fig. 538.

Let F be the point sought, and let BD be drawn meeting the circle again in G; then because from the points A, B, to the point D, two straight lines AD, BD, are inflected, and which meet the circumference again in C and G; the straight line which joins CG, will, by hypothesis, pass through the same point F. Again, draw AG, and because from the points A, B, to G, the straight lines AG, BG, are inflected one of which, as BG, meets the circumference again in D, the straight line which joins the point D, and the point of intersection of the remaining line AG and the circle, will also, by hypothesis, pass through the point F; therefore DF, when drawn, will pass through the point where AG intersects the circle: but DF meets the circumference in E. Wherefore the point E is the intersection of AG and the circumference, that is the points A, G, E, are in a straight line.

Let EH, drawn parallel to AB, meet the circumference again in H, and let DH joined meet AB in K. Then because from the points A, B, the straight lines AC, BC, are inflected to the circumference meeting it again in D and E, and EH is parallel to AB, and DH meets AB at K, the rectangle $BA \cdot AK = CA \cdot AD^*$, therefore B, K, D, C are in a circle, and consequently the rectangle $AKD = DCE = AGD$ (22. III.). therefore the points A, K, G, D, are in a circle; consequently $AB \cdot BK = DB \cdot BC = CB \cdot BE$. Therefore because it has been shewn that $BA \cdot AK = CA \cdot AD$, and $AB \cdot BK = CB \cdot BE$; $CA \cdot AD + CB \cdot BE$ will be $= BA \cdot AK + AB \cdot BK$, that is, $= AB^*$. Let M be the centre of the circle, and let MK, when joined, meet the circumference in N, and O, then MK is perpendicular to AB, and consequently to HF (Prop. I.). Therefore, because HE is perpendicular to the diameter NO, and HD is drawn to the circumference and meets the diameter in K, the straight line ED passes through a given point in the diameter, viz: that which divides it in the same

* Prop. 55: De Porismatibus. The Demonstration is evident.

ratio as NK to KO^* . But DE , by hypothesis, passes through a given point F , therefore F is in the diameter: for if not, there would be two points given in the straight line DE , and consequently it would be given by position; but this is contrary to the hypothesis. Therefore DE passes through a given point, when $AB^2 = CA \cdot AD + CB \cdot BE$, and the point F is found by making $NK : KO :: NF : FO$.

COMPOSITION. Let there be two given points A, B , and to any point in the circumference of the circle CDE given by position, let AC, BC , be inflected meeting it again in D and E , and let $AB^2 = CA \cdot AD + CB \cdot BE$; then DE , when joined, will pass through a given point F , which is found by drawing MK through the centre M perpendicular to AB , and making $NK : KO :: NF : FO$.

For, let KD be joined meeting the circle again in H , and let DE meet the diameter in F , and join HE : then because $CA \cdot AD + CB \cdot BE = AB^2$, and MK is drawn perpendicular to AB , $BA \cdot AK = CA \cdot AD$; therefore HE is parallel to AB , and consequently perpendicular to diameter NMO . And because HD meets the diameter in K , and DE meets it in F , $NK : KO :: NF : FO$: but NK and KO are given, therefore the point F is given through which DE passes. *Q. E. D.*

CASE II. When the straight line which joins the given points A, B , meets the circle. Fig. 539.

It may be shewn as in *Case 1*, that, $BA \cdot AK = CA \cdot AD$, and $AB \cdot BK = CB \cdot BE$, therefore $CA \cdot AD = (BA \cdot AK - AB \cdot BK + AB^2) = CB \cdot BE + AB^2$, and if MK be drawn to the centre it will be perpendicular to AB (Prop. II.), and consequently to HE ; therefore because HE is perpendicular to the diameter NO , and HD is drawn to the circumference and meets the diameter in K , the straight line DE passes through a given point in the diameter produced [†]; but, by hypothesis, DE passes through a given point F , therefore F is in the diameter produced. For, if it is not, two points will be given in the straight line DE , and consequently it would be given by position, but this is contrary to the hypothesis; therefore DE passes through a given point when $CA \cdot AD = CB \cdot BE + AB^2$, and the point F is found by making $NK : KO :: NF : FO$.

DR. SIMSON then gives the *Composition*, but as it differs so little from that of the first case we shall omit it.

* Prop. 51, *De Porismatisbus, or Prop. 156, Lib. 7. Pap. or Prop. 7, Lawson.*

† *Lawson's 7th Proposition.*

Ingenious solutions were also received from Messrs. Hill, Rutherford, Thornaby, and Whalley.

Mr. Swale is requested to send to Mr. Glendinning's for the Medal for solving the Prize Question.

ARTICLE V.

MATHEMATICAL QUESTIONS.

To be answered in Number XIV.

I. QUESTION 271, by Merones Minor.

SUPPOSE a man has a calf which at the end of three years begins to breed, and afterwards brings a female calf every year; and that each calf begins to breed in like manner at the end of three years, bringing forth a cow calf every year; and that these last breed in the same manner &c.; to determine the owners whole stock at the end of 30 years.

II. QUESTION 272, by Mr. W. Marrat, Boston.

A tub full of water, in form of a conical frustum, the inner dimensions of which are as follow, viz. the top and bottom diameters 20 and 30; and the perpendicular altitude 25 inches, being set upon an inclined plane, 2 gallons ale measure were observed to run over. What was the plane's inclination to the horizon?

III. QUESTION 273. by Mr. Olinthus Gregory, Cambridge.

The curve surface of a cone is 753.98232 inches, and its solidity is 2412.743424 inches: it is required to find at what distance from the vertex of the cone (measuring on the flant side) an unguла must be cut off by a vertical plane, so as to take away a fifth of the curve surface?

IV.

IV. QUESTION 274, *by Miss Susan May.*

Two given weights as y and z ,
 Connected by a silken thread,
 Suspended o'er a pulley are,
 Whose radius we'll denote by r ;
 A motion will of course ensue,
 (The great will still the small subdue);
 The pressure on the pulley's axe,
 Ye learned youths is what I ask?

V. QUESTION 275, *by Merones Minor.*

Fig. 536, pl. 28, AEB is a semicircle, BD is perpendicular and equal to AB, the diameter; DFM is any right line drawn from D, cutting the circumference in F and the diameter in M, and MP is perpendicular to AB and equal to MF. Required the quadrature of the curve which is the locus of P?

VI. QUESTION 276, *by Mr. W. Peacock, Birmingham.*

A spherical ball of copper fixed to the end of a slender rod whose length was l inches, and weight w ounces, was observed to make v vibrations in s seconds: Quere the weight of the ball?

VII. QUESTION 277, *by the Rev. David Davies, Swansea.*

A cylinder is just immersed in a fluid with its axis perpendicular to the surface; find at what point it must be cut by a plane perpendicular to its axis, that the pressures upon the convex surfaces may be equal?

VIII. QUESTION 278, *by the Rev. D. Davies.*

A body falls freely by the force of gravity down AB, and uniformly describes the space BD equal to twice AB on the horizontal plane with the velocity acquired: Determine geometrically the length and inclination of a plane drawn from A to BD, the time down which may be equal to the time down AB and along BD.

IX. QUESTION 279, by Amicus.

Two equal bodies A and B move at the same time from a point in the periphery of a given circle the one along the periphery and the other along a chord given by position.—They move in such a manner that the straight line connecting them always passes through the centre of the circle: it is required to determine the nature of the track described by the centre of gravity of the two bodies?

X. QUESTION 280, by Miss May.

Required the area of the greatest rectangle that can be inscribed in the harmonic curve whose base is 20 and height 2?

XI. QUESTION 281, by Mr. John Dawes, Birmingham.

Given the sum of the distances between the centres of the sun (S), moon (L), and a fixt star (A) = $183^{\circ} 18'$; the \angle ASL = 60° , and the \angle ALS = $107^{\circ} 20'$, to find each distance.

XII. QUESTION 282, by Mr. George Roy.

It is, I believe, pretty generally understood that the decimal obtained by extracting any root of a whole number cannot be a repetend. An investigation of this is required.

XIII. QUESTION 283, by Mr. John Andrew, Cork.

Given the difference between the segments of the base made by the point of contact with the inscribed circle and that made by the perpendicular, the difference of the sides and the line bisecting the vertical angle, to construct the plane triangle.

XIV. QUESTION 284, by Mr. W. Passman, Hull.

I demand the diameter of the greatest circle that can be inscribed in the quadrant of a given ellipse?

XV.

XV. QUESTION 285, by Mr. Nicholas Bottom.

Given the base, the verticle angle, and aggregate of the sum of the sides and line bisecting the vertical angle, to construct the plane triangle.

XVI. QUESTION 286, by Mr. Gregory.

In fig. 534, pl. 28, BC is a balance, at one end of which hangs a scale CD in which sits a man, who is counterpoised by the weight W at the end B; BF and FC being equal. Now if the man pushes a staff against the point P (FP being $\frac{2}{3}$ of FC) with a force of 8 stone in the direction DP making the angle DPC = 60° ; and the post GH prevent the scale CD from leaving its perpendicular position; it is required to find what weight must be added to, or taken from, W, so that the equilibrium may be maintained, while the pressure on P in the direction DP is exerted?

XVII. QUESTION 287, by Mr. Samuel Thornoby.

The same things being supposed as in question 287; it is required to determine when the tradesman's debt will be the greatest possible?

XVIII. QUESTION 288, by Merones Minor.

Given $l = 30$, the length; $b = 24$, the breadth; and $h = 4$, the heights of a groin formed by circular arches; to find the superficies and vacuity by a clear and general investigation?

XIX. QUESTION 289, by Mr. Johnson, Birmingham.

To find a point such that if perpendiculars be drawn from it to the sides of a given trapezium, the sum and sum of the squares of those perpendiculars may be given magnitudes.

XX. QUESTION 290, by Mr. Gregory.

For a certain period during every year there is no real night at Cambridge in latitude $52^\circ 12' 35''$ N: it is required to shew the time in the morning when the sun's azimuth from the north is a maximum, on the 1st day of this period in a place whose latitude north is half the complement of the latitude of Cambridge.

XXI:

XXI. QUESTION 291, *by Mr. Louis Hill.*

It is required to divide a right angle into three others such that their sines may obtain a given ratio?

XXII. QUESTION 292, *by Mr. Nicholas Bottom.*

If a heavy flexible line or chain, of a given length, fastened together at the ends, be suspended by a tack, at a given point upon the perfectly polished surface of a given right cone in such a manner as to include the vertex thereof: it is required to determine the portion of the convex surface included by the chain.

XXIII. QUESTION 293, *by Mr. James Cunliffe, Bolton.*

Required the sum of π terms of the series,

$$1 \cdot 2x + 2 \cdot 3x^2 + 3 \cdot 4x^3 + 4 \cdot 5x^4 + 5 \cdot 6x^5 + \text{&c. ?}$$

XXIV. QUESTION 294, *by Mr. Lowry, Birmingham.*

Given the sides of a trapezium to construct it when one of the diagonals divides the other in a given ratio.

XXV. QUESTION 295, *by Mr. Johnson, Birmingham.*

Let there be any number of straight lines Aa , Bb , Cc , Dd , &c. given by position and parallel to each other in which are the given points A , B , C , D , &c. It is required to draw a straight line to pass through a given point P , and intersect the parallels at L , M , N , O , &c. so that the sum of the squares of AL , BM , CN , DO , &c. may be equal to a given space?

XXVI. QUESTION 296, *by Mr. James Cunliffe.*

To find the least positive values of x and y in whole numbers, so that $x^2 + xy + y^2$ and $x^2 + y^2$ may be both rational squares?

XXVII. QUESTION 297, *by Mr. John Lowry.*

AB and AC are straight lines given by position and P and Q are given points. It is required to draw a straight line through Q

to meet AB, AC, in B and C, so that if BP, CP be joined, the triangle BPC may be of a given magnitude; and to shew the limits?

XXVIII. QUESTION 298, by Mr. W. Smith, Liverpool.

From a given point P, in AB, one of the sides, produced, of a given triangle ABC, it is required to draw a straight line PDE meeting the other two sides AC, BC, in D and E, so that if DE be drawn parallel to AB, the side in which is the given point, meeting BC in F, the triangle DEF may be a maximum?

XXIX. QUESTION 299, by Mr. Lowry.

From two given points A and B, situated in the circumference of a circle given in magnitude and position, it is required to draw two straight lines AEG, BEH to intersect the circle at E and meet two straight lines XG, YH, given by position, in which are the given points X, Y, at G and H, so that the sum or difference of the squares of XG, YH may be of a given magnitude.

XXX. PRIZE QUESTION 300, by Yanto.

If Q be the point in a triangle from which perpendiculars are drawn to the sides of the triangle, so that the sum of their squares is the least possible; twice the area of the triangle is a mean proportional between the sum of the squares of the sides of the triangle, and the sum of the squares of the above-mentioned perpendiculars. Required a Demonstration?

ARTICLE VI.

SIX PROPOSITIONS FROM LAWSON.

(To be answered in Number XIV.)

PROP. LV.

IN every right-angled triangle, as the difference between the hypotenuse and one side is to the difference between the same side and its adjacent segment, so is the same side to the same segment.

PROP.

PROP. LVI.

If HC be a tangent to a circle meeting the diameter DB produced in H , and from the point of contact C a perpendicular CK to that diameter be drawn, and likewise a line from H cutting the circle in F and G , and the perpendicular CK in I , and F be the nearest point to H ; then I say that the square of HF is to the square of the tangent HC as FI to IG .

PROP. LVII.

If one side AC of an equilateral triangle ABC be produced to E so that CE may be equal to AC , and from A a perpendicular to AC raised, and from E a line drawn through the vertex B to meet the perpendicular in D ; then I say that BD is equal to the radius of the circle which circumscribes the triangle.

PROP. LVIII.

If BD bisect the vertical angle B of a triangle ABC and meet the base in D , and if with either of the other angular points A or C as centre and the adjacent segment of the base as radius a circle be described to cut BD again in E ; then I say that BE is to BD as that segment used as radius is to the other.

PROP. LIX.

If BD bisect the vertical angle B of the triangle ABC , and if on BA or BC from B be put a third proportional to the other side and the bisecting line; then I say the rectangle under that side on which it is put and its remainder when the third proportional is taken from it is equal to the square of the adjacent segment of the base made by the bisecting line, that is, $BCE = CD^2$, or $BAE = AD^2$.

PROP. LX.

If an isosceles triangle be inscribed in a semi-circle and one of the equal sides produced, and if from any point E in the diameter a perpendicular thereto be drawn to cut the side, the circle, and the side produced in the points G , H , and F respectively; then I say that EG , EH , and EF are continual proportionals.

ARTICLE VII.

To the Editor of the Repository.

SIR,

IF you should look upon the following attempt to investigate the Theorem, given by Dr. Waring, for finding the sum of any power, of the roots of an equation, as deserving of a place in your valuable Repository, I should be glad if you will insert it; but if you know of any paper upon the same subject which will supersede the use of this, I must beg the favour that it may not be printed. The writer of this article having but a very confined acquaintance with Mathematical Books, there may be several demonstrations of this Rule which he has not seen.

I am, Sir, your humble servant,

A. B.

Of the Sums of the Powers of the Roots of an Equation.

LET $x^n - px^{n-1} + qx^{n-2} - rx^{n-3} + sx^{n-4} - \&c. = 0$,

be the given equation, whose roots are $a, b, c, d, \&c.$.It is well known that $\frac{1}{x-a} + \frac{1}{x-b} + \frac{1}{x-c} + \frac{1}{x-d} + \&c.$ is =

$$\frac{nx^{n-1} - (n-1)px^{n-2} + (n-2)qx^{n-3} - (n-3)rx^{n-4} + \&c.}{x^n - px^{n-1} + qx^{n-2} - rx^{n-3} + sx^{n-4} - \&c.} =$$

suppose to $M \div N$; therefore,

$$\frac{1}{x-a} - 1 + \frac{1}{x-b} - 1 + \frac{1}{x-c} - 1 + \frac{1}{x-d} - 1 = \frac{M}{N} - n,$$

the number of factors being n ; hence

$$\frac{1-x+a}{x-a} + \frac{1-x+b}{x-b} + \frac{1-x+c}{x-c} + \&c. = \frac{M-n}{N}$$

Multiply the first equation by $x-1$, then

$$\frac{x-1}{x-a} + \frac{x-1}{b} + \frac{x-1}{c} + \&c. = \frac{xM-M}{N},$$

add two equations together, and

$$\frac{a}{x-a} + \frac{b}{x-b} + \frac{c}{x-c} + \frac{d}{x-d} + \text{&c.} = \frac{xM-nN}{N}$$

$$\begin{aligned} px^{n-1} - 2qx^{n-2} + 3rx^{n-3} - 4sx^{n-4} + \text{&c.}, \\ x^n - px^{n-1} + qx^{n-2} - rx^{n-3} + sx^{n-4} + \text{&c.} \end{aligned}$$

wherefore, by actual division,

$$\left. \begin{aligned} \frac{a}{x} + \frac{a^2}{x^2} + \frac{a^3}{x^3} + \text{&c.} \\ + \frac{b}{x} + \frac{b^2}{x^2} + \frac{b^3}{x^3} + \text{&c.} \\ + \frac{c}{x} + \frac{c^2}{x^2} + \frac{c^3}{x^3} + \text{&c.} \end{aligned} \right\} = \left\{ \begin{aligned} \frac{p}{x} + \frac{p^2-2q}{x^2} + \frac{p^3-3qp+3r}{x^3} \\ + \frac{p^4-4qp^2+4rp+2q^3}{x^4} + \frac{4s}{x^4} + \text{&c.} \end{aligned} \right.$$

The homologous terms, or those where x is raised to the same power must be equal to each other, therefore

$$a + b + c + \text{&c.} = p, a^2 + b^2 + c^2 + \text{&c.} = p^2 - 2q.$$

$$a^3 + b^3 + c^3 + \text{&c.} = p^3 - 3qp + 3r,$$

$$a^4 + b^4 + c^4 + \text{&c.} = p^4 + 4qp^2 + 4rp + 2q^3 - 4s \text{ &c.};$$

for it is evident that the 1st, 2nd, 3rd, &c. numerators in the quotient, are respectively equal to the sum of the 1st, 2nd, 3rd, &c. powers of the roots of the given equation; therefore if the sum of the m th powers of the roots be required, continue the division till the quotient consists of m terms, and the numerator of the last term is the sum required.

It is evident that the *numerator* of the fraction

$$\frac{px^{n-1} - 2qx^{n-2} + 3rx^{n-3} - 4sx^{n-4} + \text{&c.}}{x^n - px^{n-1} + qx^{n-2} - rx^{n-3} + sx^{n-4} + \text{&c.}}, \text{ is found by multi-}$$

plying the terms of the given equation respectively by the terms of the following series, viz. 0, - 1, - 2, - 3, - &c.

Because the co-efficients $p, q, r, s, \text{ &c.}$ are quantities of one, two, three, &c. dimensions, if therefore the sum of the m th powers of the roots be wanted in any equation of n dimensions (n being greater than m) the numerator of the m th term in the quotient given by reducing, or dividing the following fraction, viz.

$$\frac{px^{n-1} - 2qx^{n-2} + 3rx^{n-3} \dots \dots \dots \mp mw x^{k-m}}{x^n - px^{n-1} + qx^{n-2} \dots \dots \dots \pm wx^{n-m}} =$$

$$\frac{px^{m-1} - 2qx^{m-2} + 3r^{m-3} \dots \dots \dots \mp mw}{x^m - px^{m-1} + qx^{m-2} \dots \dots \dots \pm w}, \text{ will be the sum}$$

required.

From the above it follows as an evident corollary that because

$$\frac{px^{n-1} - 2qx^{n-2} + 3rx^{n-3} - 4sx^{n-4} + \text{&c.}}{x^n - px^{n-1} + qx^{n-2} - rx^{n-3} + \text{&c.}}$$

$$\left. \begin{aligned} & \left. \begin{aligned} & \frac{a^0}{a} + \frac{a^1}{x^0} + \frac{a^2}{x^3} + \frac{a^3}{x^4} + \text{&c.} \\ & + \frac{b^0}{x} + \frac{b^1}{x^0} + \frac{b^2}{x^3} + \frac{b^3}{x^4} + \text{&c.} \\ & + \frac{c^0}{x} + \frac{c^1}{x^0} + \frac{c^2}{x^3} + \frac{c^3}{x^4} + \text{&c.} \end{aligned} \right\} \\ & \text{in infinitum,} \\ & \text{therefore, if } x = 1, \\ & \text{&c. &c. &c. &c.} \end{aligned} \right\}$$

$$\frac{p - 2q + 3r - 4s + \text{&c.}}{1 - p + q - r + s - \text{&c.}} = \left\{ \begin{aligned} & a + b + c + \text{&c.} \\ & + a^0 + b^0 + c^0 + \text{&c.} \\ & + a^1 + b^1 + c^1 + \text{&c.} \end{aligned} \right. \text{ in infinitum}$$

that is, the sum, of the sum of the roots, the sum of the squares, cubes, &c. in infinitum of an equation of n dimensions is equal to

$$\frac{p - 2q + 3r - 4s + \text{&c.}}{1 - p + q - r + s - \text{&c.}}, \text{ if that sum be finite.}$$

To find the sum of the m th powers of their roots:

$$\text{Put } R = \frac{p}{x^0} - \frac{q}{x^1} + \frac{r}{x^2} - \frac{s}{x^3} + \text{&c.} \text{ then because}$$

$$\frac{1}{1-R} = 1 + R^0 + R^1 + R^2 + \text{&c.} \text{ therefore.}$$

$$\frac{px^{n-1} - 2qx^{n-2} + 3rx^{n-3} - 4sx^{n-4} + \text{&c.}}{x^n - px^{n-1} + qx^{n-2} - rx^{n-3} + sx^{n-4} + \text{&c.}} =$$

$$\left(\frac{p}{x} - \frac{2q}{x^0} + \frac{3r}{x^1} - \text{&c.} \right) \div \left(1 - \frac{p}{x} + \frac{q}{x^0} - \frac{r}{x^1} + \text{&c.} \right) =$$

$$\left(\frac{p}{x} - \frac{2q}{x^0} + \frac{3r}{x^1} - \text{&c.} \right) \times \left(1 + R + R^0 \dots R^{m-2} + R^{m-1} \text{&c.} \right) =$$

H 2

$$\left(\frac{p}{x} - \frac{2q}{x^2} + \frac{3r}{x^3} - \text{&c.} \right) \times \left(R^{m-1} + R^{m-2} + R^{m-3} \dots R + 1 \right).$$

Hence by substituting the value of R, we shall have,

$$\left. \begin{aligned} & \left. \begin{aligned} & \frac{a}{x} + \frac{a^2}{x^2} + \frac{a^3}{x^3} \dots + \frac{a^m}{x^m} \text{ &c.} \\ & + \frac{b}{x} + \frac{b^2}{x^2} + \frac{b^3}{x^3} \dots + \frac{b^m}{x^m} \text{ &c.} \\ & + \frac{c}{x} + \frac{c^2}{x^2} + \frac{c^3}{x^3} \dots + \frac{c^m}{x^m} \text{ &c.} \\ & \text{&c. &c. &c.} \end{aligned} \right\} = \left(\frac{p}{x} - \frac{2q}{x^2} + \frac{3r}{x^3} - \text{&c.} \right) \times \\ & \left. \begin{aligned} & \left. \begin{aligned} & \frac{1}{x^{m-1}} \left(p - \frac{q}{x} + \frac{r}{x^2} - \frac{s}{x^3} + \frac{t}{x^4} - \text{&c.} \right)^{m-1} \\ & + \frac{1}{x^{m-2}} \left(p - \frac{q}{x} + \frac{r}{x^2} - \frac{s}{x^3} + \frac{t}{x^4} - \text{&c.} \right)^{m-2} \\ & + \frac{1}{x^{m-3}} \left(p - \frac{q}{x} + \frac{r}{x^2} - \frac{s}{x^3} + \frac{t}{x^4} - \text{&c.} \right)^{m-3} \\ & + \frac{1}{x^3} \left(p - \frac{q}{x} + \frac{r}{x^2} - \frac{s}{x^3} + \frac{t}{x^4} - \text{&c.} \right)^3 \\ & + \frac{1}{x^2} \left(p - \frac{q}{x} + \frac{r}{x^2} - \frac{s}{x^3} + \frac{t}{x^4} - \text{&c.} \right)^2 \\ & + \frac{1}{x} \left(p - \frac{q}{x} + \frac{r}{x^2} - \frac{s}{x^3} + \frac{t}{x^4} - \text{&c.} \right) \\ & + 1 \end{aligned} \right\} \end{aligned} \right]$$

It is evident from the mere inspection of the last equation, that the first term of the highest line, the second of the next, the third of the next following, &c. are homologous, or contain the same power of x ; viz. $\frac{1}{x^{m-1}}$; or more generally, the first term

of any line, the second of the line below, the third in the next following, &c. are homologous. If therefore we put

A, A', A'', &c. for the 1st terms of $R^{m-1}, R^{m-2}, R^{m-3}, \text{&c.}$ respectively;

B, B', B'', &c. for the 2d terms of $R^{m-2}, R^{m-3}, R^{m-4}, \text{&c.}$

C, C', C'', &c. for the 3d terms of $R^{m-3}, R^{m-4}, R^{m-5}, \text{&c.}$

D, D', D'', &c. for the 4th terms of $R^{m-4}, R^{m-5}, R^{m-6}, \text{&c. &c.}$

Then it is evident, after expanding and multiplying, that

$$\left. \begin{array}{l} p \times (A + B + C + D + \text{&c.}) \\ - 2q \times (A' + B' + C' + D' + \text{&c.}) \\ + 3r \times (A'' + B'' + C'' + D'' + \text{&c.}) \\ - 4s \times (A''' + B''' + C''' + D''' + \text{&c.}) \\ \text{&c. &c.} \end{array} \right\} = a^m + b^m + c^m + d^m + \text{&c.}$$

For the homologous terms must be equal, and the same power of x , viz. $\frac{1}{x^m}$ enters into every term, which therefore may be neglected.

We must next determine the values of $A, A', A'', \text{ &c. } B, B', B'', \text{ &c. } C, C', C'', \text{ &c. &c.}$ neglecting x , or calling it unity; then these values being substituted in the last equation, will give the sum of the m th power of the roots.

By Emerson's Algebra, page 151,

$$\left. \begin{array}{l} R^{m-1} = p^{m-1} - (m-1) qp^{m-2} + (m-1) \left(\frac{m-2}{2} \right) q^2 p^{m-3} \\ \quad \quad \quad + (m-1) rp^{m-2} \\ \quad \quad \quad - (m-1) \left(\frac{m-2}{2} \right) \left(\frac{m-3}{3} \right) q^3 p^{m-4} \\ \quad \quad \quad - (m-1) \left(\frac{m-2}{2} \right) 2qr p^{m-3} \\ \quad \quad \quad - (m-1) sp^{m-2} \\ \quad \quad \quad + (m-1) \left(\frac{m-2}{2} \right) \left(\frac{m-3}{3} \right) \left(\frac{m-4}{4} \right) q^4 p^{m-5} \\ \quad \quad \quad + (m-1) \left(\frac{m-2}{2} \right) \left(\frac{m-3}{3} \right) 3q^2 r p^{m-4} \\ \quad \quad \quad + (m-1) \left(\frac{m-2}{2} \right) (2qs + r^2) p^{m-3} \\ \quad \quad \quad + (m-1) ts p^{m-2} \\ \quad \quad \quad \text{&c.} \end{array} \right\}$$

Hence by substituting $m-1, m-2, m-3, \text{ &c.}$ for $m-1$, the several values of $A, A', A'', \text{ &c. } B, B', B'', \text{ &c. } C, C', C'', \text{ &c.}$ will be found as follow.

$$\begin{array}{ll} A = p^{m-1}, & B = -(m-2) qp^{m-3} \\ A' = p^{m-2}, & B' = -(m-3) q^2 p^{m-4}, \\ A'' = p^{m-3}, & B'' = -(m-4) q^3 p^{m-5}, \\ \text{&c.} & \text{&c.} \end{array}$$

H 3

C =

$$C = \left\{ \begin{array}{l} (m-3) \, rp^{m-4} \\ + (m-3) \left(\frac{m-4}{4} \right) q^2 p^{m-5} \end{array} \right.$$

$$C = \left\{ \begin{array}{l} (m-4) \, rp^{m-5} \\ + (m-4) \left(\frac{m-5}{2} \right) q^2 p^{m-6} \end{array} \right.$$

$$C' = \left\{ \begin{array}{l} (m-5) \, rp^{m-6} \\ + (m-5) \left(\frac{m-6}{2} \right) q^2 p^{m-7} \\ \text{&c.} \qquad \qquad \qquad \text{&c.} \end{array} \right.$$

$$D = \left\{ \begin{array}{l} -(m-4) \, sp^{m-5} \\ - (m-4) \left(\frac{m-5}{2} \right) \, 2qrp^{m-6} \\ - (m-4) \left(\frac{m-5}{2} \right) \left(\frac{m-6}{3} \right) qrp^{m-7} \end{array} \right.$$

$$D' = \left\{ \begin{array}{l} -(m-5) \, sp^{m-6} \\ - (m-5) \left(\frac{m-6}{2} \right) \, 2qrp^{m-6} \\ - (m-5) \left(\frac{m-6}{2} \right) \left(\frac{m-7}{3} \right) qrp^{m-8} \end{array} \right.$$

$$D'' = \left\{ \begin{array}{l} -(m-6) \, sp^{m-7} \\ - (m-6) \left(\frac{m-7}{2} \right) \, 2qrp^{m-8} \\ - (m-6) \left(\frac{m-7}{2} \right) \left(\frac{m-8}{3} \right) qrp^{m-9} \\ \text{&c.} \qquad \qquad \qquad \text{&c.} \end{array} \right.$$

$$E = \left\{ \begin{array}{l} (m-5) \, tp^{m-6} \\ + (m-5) \left(\frac{m-6}{2} \right) (2qs + r^2) p^{m-7} \\ + (m-5) \left(\frac{m-6}{2} \right) \left(\frac{m-7}{3} \right) 3qr^2 p^{m-8} \\ + (m-5) \left(\frac{m-6}{2} \right) \left(\frac{m-7}{3} \right) \left(\frac{m-8}{4} \right) q^2 p^{m-9} \end{array} \right.$$

$$E' =$$

$$E = \left\{ \begin{array}{l} + (m-6) sp^{m-7} \\ + (m-6) \left(\frac{m-7}{2}\right) (2qs + r) p^{m-8} \\ + (m-6) \left(\frac{m-7}{2}\right) \left(\frac{m-8}{3}\right) 3qr p^{m-9} \\ + (m-6) \left(\frac{m-7}{2}\right) \left(\frac{m-8}{3}\right) \left(\frac{m-9}{4}\right) q^4 p^{m-10} \\ \text{&c.} \end{array} \right. \quad \text{&c.}$$

Wherefore by substituting in the equation,

$$a^m + b^m + c^m + d^m = \left\{ \begin{array}{l} p \times (A + B + C + D + \text{&c.}) \\ - 2q \times (A' + B' + C' + D' + \text{&c.}) \\ + 3r \times (A'' + B'' + C'' + D'' + \text{&c.}) \\ - 4s \times (A''' + B''' + C''' + D''' + \text{&c. &c.}) \end{array} \right.$$

the values of A, B, C, &c. &c. found above, we shall have as follows

$$p \times (A + B + C + \text{&c.}) = \left\{ \begin{array}{l} p^m - (m-2) qp^{m-2} \\ + (m-3) rp^{m-3} \\ + (m-3) \left(\frac{m-4}{2}\right) q^2 p^{m-4} \\ - (m-4) sp^{m-4} \\ + (m-5) t p^{m-5} \\ - (m-4) \left(\frac{m-5}{2}\right) 2qr p^{m-5} \\ - (m-6) up^{m-6} \\ + (m-5) \left(\frac{m-6}{2}\right) (2qs + r^2) p^{m-6} \\ - (m-4) \left(\frac{m-5}{2}\right) \left(\frac{m-6}{3}\right) q^3 p^{m-6} \end{array} \right.$$

$$- 2q \times (A' + B' + C' + \text{&c.}) = \left\{ \begin{array}{l} - 2qp^{m-2} + (m-3) 2q^2 p^{m-4} \\ - (m-4) 2qr p^{m-5} \\ - (m-4) \left(\frac{m-5}{2}\right) 2q^3 p^{m-6} \\ + (m-5) 2qs p^{m-6} \end{array} \right.$$

$$\begin{aligned}
 + 3r \times (A'' + B'' + C'' + \&c.) &= \left\{ \begin{array}{l} 3rp^{m-3} - (m-4)3qrp^{m-5} \\ \quad + (m-5)3rp^{m-6} \end{array} \right\} \&c. \\
 - 4s \times (A'' + B'' + C'' + \&c.) &= - 4sp^{m-4} + (m-5)4qsp^{m-6} \&c. \\
 + 5t \times (A'' + B'' + C'' + \&c.) &= + 5tp^{m-5} \&c. \\
 - 6u \times (A'' + B'' + C'' + \&c.) &= 6up^{m-6} \&c.
 \end{aligned}$$

$$\begin{aligned}
 \text{Hence by addition, } a^m + b^m + c^m + \&c. &= \left\{ \begin{array}{l} p^m - mqp^{m-2} + mrp^{m-3} \\ \quad - ms \\ \quad + m(\frac{m-3}{2})q \end{array} \right\} p^{m-4} \\
 &\quad + mt \} p^{m-5} \\
 &\quad - m(m-4)qr \} p^{m-5} \\
 &\quad - mu \\ &\quad + m(m-5)qs \\ &\quad - m(\frac{m-4}{2})(\frac{m-5}{3})qs \} p^{m-6} \&c. \\
 &\quad + m(\frac{m-5}{2})r \}
 \end{array} \right\} p^{m-6} \&c.
 \end{aligned}$$

It is evident that the theorem may be carried to any number of terms by the method given above.

ARTICLE VIII.

To the Editor of the Repository.

SIR,

IF the following paper (for the contents of which I am indebted chiefly to Montucla's *Histoire des Mathematiques*; and Bailly's *Histoire de L'Astronomie Moderne*;) be thought worthy of a place in your *Miscellany*, the insertion of it will oblige, Sir, your's, &c.

R. March 1st, 1802.

L. R.

An attempt towards a Restitution of the lost Treatise of Eratosthenes, "de Locis ad Medietates".

ERATOSTHENES (born at Cyrene 271 years before CHRIST;) was one of those great and extraordinary men, whose minds embrace every

every species of human knowledge :—He was called the Surveyor of the universe, the Cosmographer ;—the second Plato. His reputation for learning was so great, that he was invited from Athens to Alexandria, by Ptolemy Euergetes, and made by him keeper of the Royal Library at Alexandria, in which employment he died, in the 80th year of his age. It was at his request, that the same Ptolemy erected those armillas, or circles of brass, in the portico at Alexandria, with which Hipparchus, and Ptolemy, afterwards, so successfully observed the heavenly bodies. He was the first who attempted to measure the Earth, and the method which he invented for this purpose, would, alone, have rendered his name immortal. He also invented the Astrolabe, with which he undertook to measure the obliquity of the ecliptic ; and it is singular that the distance of the Sun from the Earth, which he estimated at 804,000,000 stadia, is exactly conformable to the distance assigned by Cassini, and Dé la Caille. The works, that remain, of this excellent poet, grammarian, mathematician, and astronomer, were printed in an 8vo. volume, at Oxford, in the year 1672, and again at Amsterdam, in 1703.

In the mathematics, his attention was principally directed to geometry and astronomy : He indeed deserved to be ranked with the celebrated geometers of antiquity, *Aristeus*, *Euclid*, and *Apollonius*, who had written on geometrical analysis :—*Pappus*, in the preface to his 7th book, mentions a treatise of his (now lost,) in two books, entitled, “*de Loci de Medietates*”, the object of which was to promote that analysis ; it is greatly to be lamented, that *Pappus* has left us no abstract of this work ; he has given a sketch of the contents of several geometrical treatises, that are now lost, but he has done little more than announce the title of this.

Most of the lost treatises, of the ancient geometers, have been restored by the moderns, but the restitution of this has never yet been attempted, by any person, that I know of : I shall however in what follows give a brief sketch of what appears to me to have formed the two principal propositions in this work, leaving the task of demonstrating them, to others.

It must be observed, in the first place, that, according to *Pappus*, these “*Loci ad Medietates*,” were *Conic Sections* ; and farther, that, with the ancients, *Mediatate*, (or *Mediety*,) was a *general term*, invented to express three Lines, having either an arithmetical, a geometrical, or an *harmonical* relation ; but the words *proportion*, (or *ratio*,) and *analogy* were restricted to *geometrical relation* only.

This being premised, I think it is extremely probable, that the two following theorems have been the subject of the lost work of *Eratosthenes* ;—If I am mistaken, I hope my readers will at least give me credit for having noticed two properties of the *conic sections*

sections which are not mentioned by any author I have read on that subject.

THEOREM I. *Fig. 542, Plate xxix.*

Let there be two right lines AB , CD , any how drawn, let the right line GH , be taken as an axis, and draw the line OF , making any angle whatever with GH ; then, if the point P , (or p , or π , &c.) be so situated, that OP , (or Op , or $O\pi$, &c.) shall be with respect to OF , OE , in any continued arithmetical, geometrical, or harmonical mediety, whatever, *i. e.*

if $OP : OE :: OE : OF$, or if $OE : Op :: Op : OF$, or if $OE : OF :: OF : O\pi$; be in any arithmetical, geometrical, or harmonical proportion whatever; I say, that the points P (or p , or π , similarly situated,) shall be in a Conic Section.

THEOREM II. *Fig. 543, Plate xxix.*

Let three right lines, AB , CD , GH , be drawn; let any axis LGA be taken at pleasure; and draw the right line OFK , making any angle, whatever with CA ; then, if the point P be so situated, that $OP : OE :: OF : OI$, in any continued arithmetical, geometrical, or harmonical mediety, whatever; I say, that all the points P , &c. so situated, shall be in a Conic Section. And it will be the same with the points p , π , \tilde{a} , &c. *i. e.*

if $OE : OP :: OF : OI$; or if $OE : OF :: O\pi : OI$; or if $OE : OF :: OI : O\tilde{a}$, be in any continued arithmetical, geometrical, or harmonical proportion, whatever; then will the points p , π , and \tilde{a} be in a Conic Section.

These Theorems may be easily demonstrated by means of the modern analysis; for it is evident that the dimensions of the co-ordinates can never exceed the second degree. It is also evident, that, if they were treated after the manner of the ancients, and if the different cases which they admit of, were all separately examined and investigated, they would afford ample matter for two books, one of which might contain the *first*, its cases, corollaries, &c. and the other the *second*.

For a further account of Eratosthenes, and his writings, see Vol. 1st of Montucla's Hist. des Math. before mentioned, page 239—280, new edit. Paris 1799. And Bailly's Hist. de l'Astron. Moderne, B. I. Vol. I. And Phil. Trans. 1772.

ARTICLE IX.

To the Editor of the Mathematical Repository.

SIR,

IF the following observations on the Fraction whose numerator and denominator vanish, should be thought worthy of a place in your valuable Repository, by inserting the same you will greatly oblige,

Sir,

Your most obedient humble Servant,
Hull Citadel, Sept. 8, 1802.

W.C.

Observations from a Periodical Publication.

" In this difficulty among mathematicians, I shall observe only, that when a fraction appears by assigning a peculiar value to the variable quantity under the form $\frac{0}{0}$, the fraction in that instance ceases to exist, and the supposition that it can have a determinate value, arose merely from inattention to the fraction in this supposed determinate state.

" For example, $\frac{ax - x^2}{ax^2 - x^3}$ appear in the form $\frac{0}{0}$, when x is equal to a ; consequently, to use the common Rule, the fraction has in this case a determinate value, which is $\frac{ax - 2xx}{2axx - 3x^2x}$, or

$\frac{a - 2x}{2ax - 3x^2}$, which, when x is equal to a , becomes $\frac{1}{a}$; that is, the fraction has the determinate value of $\frac{1}{a}$, when x is equal to a .

Common sense recoils at this determination, when it puts the algebraical terms into numbers, and making a equal to ten feet, and supposing x equal to it, the fraction appears to be $\frac{100 - 100}{1000 - 1000}$, or nothing at all; and on examining the fraction

we see that it really is equal to $\frac{x \times (a - x)}{x^2 \times (a - x)}$, or $\frac{x}{x^2}$, or $\frac{1}{a}$, since $a - x$, divided by $a - x$, gives unity. But this supposed quo-

* The common rule for finding the value of a fraction whose numerator and denominator vanish, being to divide the fluxion of the numerator by the fluxion of the denominator.

tient

tient cannot be true, when $a - x$ ceases to be a number, and in that case the fraction is $\frac{1}{a} \times \frac{0}{0}$, or nothing at all, as it evidently ought to be. The fact shews itself at once to the person who would draw the curve corresponding to the equation $y = \frac{ax - x^2}{ax^2 - x^3}$, in which it is evident that all the ordinates will be greater than $\frac{1}{a}$; but as when x ceases to exist, no corresponding ordinate can be drawn to the curve, so no ordinate can be drawn when x becomes equal to a ; and annihilates the relationship between y and x . The length of y extends without limit as the abscissa is decreased, it diminishes as x increases, and its limit of decrease is $\frac{1}{a}$." Thus far the quotation.

Observations on the foregoing, by W. C.

In order to examine how far our writer's reasoning in the above paragraph may be consistent with mathematical demonstration, let us begin where he says, that the quotient of $a - x$ divided by $a - x$ cannot be equal to unity when $a - x$ ceases to be a number; now it is well known by every school boy that whilst $a - x$ remains a number, though infinitely small, the quotient of $a - x$ divided by $a - x$ must be equal to unity; and when $a - x$ ceases to be a number it is manifest that $\frac{a - x}{a - x} = \frac{0}{0} = 0^1 \div 0^1 = 0^{1-1} = 0^0$, this last expression has been pretty well handled at pages 398 and 399 vol 1. of the Math. Repository and there proved equal to 1; but at the same time the writer, on page 399 ibid. seems to hint that $\frac{0}{0}$ and 0^0 are not the same or equal, however my humble opinion is, that, from above it is very evident the two expressions are equal when 0 does actually represent no number at all, and consequently our question now is to find the value of 0^0 or $\frac{0}{0}$?

First for 0^0

Since the log. of $1 - z$ is $-z - \frac{1}{2}z^2 - \frac{1}{3}z^3 - \frac{1}{4}z^4 - \&c.$

ad infinitum we shall have the log of $1 - z$

$$= 1 - z \text{ into } -z - \frac{1}{2}z^2 - \frac{1}{3}z^3 - \frac{1}{4}z^4 - \frac{1}{5}z^5$$

$$= z^0 + \frac{1}{2}z^1 + \frac{1}{3}z^2 + \frac{1}{4}z^3 + \frac{1}{5}z^4 + \&c. - z - \frac{1}{2}z^2 - \frac{1}{3}z^3 - \frac{1}{4}z^4 + \&c.$$

which when z is equal to 1 will be

$1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \dots$ &c. — $1 - \frac{1}{2} - \frac{1}{3} - \frac{1}{4} - \dots$ &c. = 0, whence the log. of $0^0 = 0$, and therefore 0^0 is equal to 1.

Secondly for $\frac{0}{0}$.—Because the log. of $1 - 1 = 0$ is $-1 - \frac{1}{2} - \frac{1}{3} - \frac{1}{4} - \dots$ &c., the log. of $\frac{0}{0}$ will be $(-1 - \frac{1}{2} - \frac{1}{3} - \frac{1}{4} - \dots)$ &c.) minus $(-1 - \frac{1}{2} - \frac{1}{3} - \frac{1}{4} - \dots)$ &c.) = 0, which is the log. of 1. Hence we see that 0^0 and $\frac{0}{0}$ are each equal to unity; and consequently 0^0 is equal to $\frac{0}{0}$. Much more might be said on this head but I shall leave it to abler hands.

Now to draw the curve corresponding to the equation $y = \frac{ax - x^3}{ax^2 - x^3}$; from what has been already done, it will manifestly appear that y ($= \frac{ax - x^3}{ax^2 - x^3}$) will always be $= \frac{1}{x}$, for when $x = 0$, then $\frac{ax - x^3}{ax^2 - x^3} = \frac{1}{x} \times \frac{x}{x} \times \frac{a - x}{a - x}$ will be $= \frac{1}{0} \times \frac{0}{0} \times \frac{a - 0}{a - 0} = \frac{1}{0}$, because $\frac{0}{0} = 1$; and when $x = a$, then $\frac{ax - x^3}{ax^2 - x^3} = \frac{1}{a} \times \frac{a}{a} \times \frac{0}{0} = \frac{1}{a}$ and for any other value of x than these two, it is evident that $y = \frac{1}{x}$, whence, making the ordinate (y) every where $= \frac{1}{x}$, a line being drawn through the extremity thereof will represent the curve required.—

How our writer should imagine that the limit of y is $\frac{1}{a}$, I must leave to the judgment of the worthy and able correspondents of the Mathematical Repository, and sincerely wish success may attend the labours of every true lover of the Mathematics.

ARTICLE X.

Answer to Question 238 proposed in No. X. Translated from Golovin's Russian Edition of Euler's Theory on Ship-Building. Communicated by Mr. George Sanderson.

QUESTION.

IF there be three arches or angles δ , η , ϕ , where δ is given,

I

the

the expression $\frac{\sin. (\delta - n - \phi)}{\sin. \phi} \times \sqrt{\cos. n}$ will be the greatest possible when the $\tan. (\delta - n) = \frac{1}{2} \tan. n \times \frac{2 - \tan. n \times \tan. \phi}{\frac{1}{2} - \tan. n \times \tan. \phi}$; the relation between the angles n and ϕ being expressed by the equation, $\cot. n = (a^3 \div 2b^3) \times \tan. \phi^3$.

SOLUTION.

When any expression is a maximum, its logarithm is a maximum also. The logarithm of

$$\frac{\sin. (\delta - n - \phi)}{\sin. \phi} \times \sqrt{\cos. n} = 1. \sin. (\delta - n - \phi) + \frac{1}{2}$$

$$1. \cos. n - 1. \sin. \phi.$$

The fluxion of this being made $= 0$ gives

$$\frac{\text{flux.} (\delta - n - \phi) \times \cos. (\delta - n - \phi)}{\sin. (\delta - n - \phi)} - \frac{\dot{n} \times \sin. n}{2 \cos. n} - \frac{\dot{\phi} \times \cos. \phi}{\sin. \phi} = 0:$$

But, δ being a constant quantity, by the question, the fluxion of $(\delta - n - \phi)$ will be $= -\dot{n} - \dot{\phi}$; therefore

$$\frac{-(\dot{n} + \dot{\phi}) \times \cos. (\delta - n - \phi)}{\sin. (\delta - n - \phi)} - \frac{\dot{n} \times \sin. n}{2 \cos. n} - \frac{\dot{\phi} \times \cos. \phi}{\sin. \phi} = 0.$$

But $\cot. n = \frac{a^3}{2b^3} \times \tan. \phi^3$, therefore

$$1. \cot. n = 1. \frac{a^3}{2b^3} + \text{sl. tan. } \phi; \text{ taking the fluxions,}$$

$$\frac{-\dot{n}}{\sin. n \times \cos. n} = \frac{2\dot{\phi}}{\sin. \phi \times \cos. \phi}; \text{ this being reduced gives,}$$

$$\dot{n} = -\frac{2\dot{\phi} \times \sin. n \times \cos. n}{\sin. \phi \times \cos. \phi}: \text{ hence}$$

$-(\dot{n} + \dot{\phi}) = \frac{2\dot{\phi} \times \sin. n \times \cos. n}{\sin. \phi \times \cos. \phi} - \dot{\phi}$. Let these values of \dot{n} and $-(\dot{n} + \dot{\phi})$ be written in the expression

$$\frac{-(\dot{n} + \dot{\phi}) \times \cos. (\delta - n - \phi)}{\sin. (\delta - n - \phi)} - \frac{\dot{n} \times \sin. n}{2 \cos. n} - \frac{\dot{\phi} \times \cos. \phi}{\sin. \phi} = 0, \text{ & we get}$$

$\infty \times$

$$\left. \begin{aligned} & \frac{2 \times \phi \times \sin. \eta \times \cos. \eta \times \cos. (\delta - \eta - \phi)}{\sin. \phi \times \cos. \phi \times \sin. (\delta - \eta - \phi)} - \frac{\phi \times \cos. (\delta - \eta - \phi)}{\sin. (\delta - \eta - \phi)} \\ & + \frac{\phi \times \sin. \eta^*}{\sin. \phi \times \cos. \phi} - \frac{\phi \times \cos. \phi}{\sin. \phi} \end{aligned} \right\} = 0, \text{ or}$$

$$\left. \begin{aligned} & \frac{2 \sin. \eta \times \cos. \eta \times \cos. (\delta - \eta - \phi)}{\sin. \phi \times \cos. \phi \times \sin. (\delta - \eta - \phi)} - \frac{\cos. (\delta - \eta - \phi)}{\sin. (\delta - \eta - \phi)} \\ & + \frac{\sin. \eta^*}{\sin. \phi \times \cos. \phi} - \frac{\cos. \phi}{\sin. \phi} \end{aligned} \right\} = 0.$$

Multiply this equation by $\frac{\sin. (\delta - \eta - \phi)}{\cos. (\delta - \eta - \phi)} = \tan. (\delta - \eta - \phi)$. Then

$$\frac{2 \sin. \eta \times \cos. \eta}{\sin. \phi \times \cos. \phi} - 1 + \frac{\sin. \eta^* \times \tan. (\delta - \eta - \phi)}{\sin. \phi \times \cos. \phi} - \frac{\cos. \phi \times \tan. (\delta - \eta - \phi)}{\sin. \phi} = 0$$

$$\text{Make } P = \frac{2 \sin. \eta \times \cos. \eta}{\sin. \phi \times \cos. \phi} - 1 \text{ and } Q = \frac{\sin. \eta^*}{\sin. \phi \times \cos. \phi} - \frac{\cos. \phi}{\sin. \phi}.$$

$$\text{Then } P + Q \times \tan. (\delta - \eta - \phi) = 0.$$

$$\text{But by trigonometry } \tan. (\delta - \eta - \phi) = \frac{\tan. (\delta - \eta) - \tan. \phi}{1 + \tan. (\delta - \eta) \times \tan. \phi}.$$

$$\text{Hence } P + Q \times \frac{\tan. (\delta - \eta) - \tan. \phi}{1 + \tan. (\delta - \eta) \times \tan. \phi} = 0, \text{ or}$$

$$P + P \times \tan. (\delta - \eta) \times \tan. \phi + Q \times \tan. (\delta - \eta) - Q \times \tan. \phi = 0.$$

$$\text{Hence } \tan. (\delta - \eta) = \frac{Q \times \tan. \phi - P}{P \times \tan. \phi + Q}. \text{ Let the values of } P \text{ and } Q \text{ be restored and we shall have}$$

$$\begin{aligned} Q \times \tan. \phi - P &= \frac{\sin. \eta^*}{\cos. \phi^*} - \frac{2 \sin. \eta \times \cos. \eta}{\sin. \phi \times \cos. \phi} \\ &= \frac{\sin. \eta \times \cos. \eta}{\sin. \phi \times \cos. \phi} \times (2 - \tan. \eta \times \tan. \phi), \text{ and} \end{aligned}$$

$$P \times \tan. \phi + Q = \frac{2 \sin. \eta \times \cos. \eta}{\cos. \phi^*} + \frac{\sin. \eta^*}{\sin. \phi \times \cos. \phi} - \frac{1}{\sin. \phi \times \cos. \phi}.$$

$$\text{But } \sin. \eta^* = 1 - \cos. \eta^*; \text{ Therefore}$$

$$\begin{aligned} P \times \tan. \phi + Q &= \frac{2 \sin. \eta \times \cos. \eta}{\cos. \phi^*} - \frac{\cos. \eta^*}{\sin. \phi \times \cos. \phi} \\ &= \frac{2 \cos. \eta^*}{\sin. \phi \times \cos. \phi} \times (\frac{1}{2} - \tan. \eta \times \tan. \phi). \end{aligned}$$

$$\begin{aligned}\text{Hence tan. } (\delta - \eta) &= \frac{Q \times \tan. \phi - P}{P \times \tan. \phi + Q} \\ &= \frac{1}{2} \tan. \eta \times \frac{\frac{2 - \tan. \eta \times \tan. \phi}{1 + \tan. \eta \times \tan. \phi}}{\frac{1 - \tan. \eta \times \tan. \phi}{1 + \tan. \eta \times \tan. \phi}}. Q. E. D.\end{aligned}$$

ARTICLE XI.

Demonstrations to Lawson's Propositions proposed in ARTICLES XXXVII and XLV, VOL. II.

PROP. XXXVII. Fig. 544, 545, Pl. 29.

Demonstrated by Mr. John Lowry.

DRRAW FH \perp to BC, and join FC. Then by Eu. 12 or 13, II,
 $AF^2 = CF^2 + AC^2 + 2AC \cdot CH$, but
 $CF^2 = AC \cdot CB$, by the hypothesis; therefore,
 $AF^2 = AC \cdot CB + AC^2 + 2AC \cdot CH$; but
 $CB + AC = 2DC$; therefore
 $AF^2 = 2AC \cdot DH = 2AC \cdot EF$. *Q. E. D.*

PROP. XXXVIII. Fig. 546, Pl. 29.

Demonstrated by Mr. John Lowry.

Let ABCD be any regular figure circumscribed about a circle whose centre is O. Let P be any point within the figure, and draw the perpendiculars PG, PH, PI, PK, &c. and join AP, BP, CP, DP, &c. Now it is evident that the sum of all the triangles APB, BPC, CPD, APD, &c. or the rectangle under one of the sides and half the sum of the perpendiculars PG, PH, PI, PK, &c. is equal to the area of the regular figure ABCD, that is, equal to the multiple of the rectangle under one side and the semi-diameter of the circle by the number of the sides of the figure. Therefore the sum of the perpendiculars will be equal to the multiple of the semi-diameter of the circle by the number of the sides of the figure.

PROP. XXXIX. Fig. 547, Pl. 29.

Demonstrated by Mr. Lowry.

Let the straight lines AB, AC, AD, AE, &c. meet the circle

circle in the points B, C, D, E, &c, and make the angles BAC, CAD, DAE, &c. equal. Then the arcs BC, CD, DE, &c. are equal. Join BD, and ED; then the angle BDE is equal to the angle BAF, that is, equal to the angle BAC. Therefore the arc BE is equal to the arc BC, and consequently the circle is divided into equal parts at the points B, C, D, E, &c.

PROP. XL. Fig. 548, 549, Pl. 29.

Demonstrated by Messrs. Cunliffe and Lowry.

In the triangle DEF draw DG making $\angle FDG = \angle D$, and meeting EF produced in G. Then $\angle FDG = \angle D$, that is by hypothesis $= \angle A$; also, by Euc. 32, I. $\angle DFG = \angle D + \angle E$, that is by hypothesis, $= \angle B$. Whence it is plain that the \triangle s ABC, DFG, are similar, therefore $CA : CB :: GD : GF$; but the $\angle GDE$ is bisected by DF; wherefore, by Euc. 3, VI. $GD : GF :: DE : EF$, and consequently $CA : CB :: DE : EF$

Q. E. D.

The same, by Tyro Philomatheticus, of Hull.

On AB and DF demit the \perp s CR and ES; then by sim. \triangle s $CA : CR :: ED : ES$; but the $\angle CBA$ being $=$ to both the \angle s FDE and FED, the $\angle CBR$ must be $=$ to $\angle DFE$ (Simp. Geom. B. I. Prop. 1 and 9); therefore by sim. \triangle s $CR : CB :: ES : EF$, hence $CA : CB :: ED : EF$.

Q. E. D.

PROP. XLI. Fig. 550, 551, 552. Pl. 29.

Demonstrated by Mr. James Cunliffe, Fig. 550.

Let ACB be a \triangle having the vertical $\angle C$ bisected by the line CD meeting the base in D. Draw AE and BF \perp to CD, and bisect CD in m, and in CD take CF $=$ DF.

It is evident that the \triangle s CAE and CBF, as well as the \triangle s AED and BFD are similar. Therefore
 $CE : CF :: AE : BF :: DE : DF$, and alternately
 $CE : DE :: CF : DF$; therefore by division
 $CD = 2mD : DE :: CF - DF = 2mF : DF$, or
 $mD : DE :: mF : DF$, and by composition
 $mE : DE :: mD : DF$; consequently
 $mD : mF :: mE : mD$; Whence Euc. 17, VI.
 $mF \cdot mE = (mD)^2$, or $2mE \cdot 2mF = 4(mD)^2 = CD^2$.

Now by the cor. to Prop. 24, B. II. of Emerson's Geom.
 $BC^2 - BD^2 = 2mF \cdot CD$, and $AC^2 - AD^2 = 2mE \cdot CD$, whence

I g

$(BC^2 - BD^2) - (AC^2 - AD^2) = 2mE \cdot CD - 2mF \cdot CD = 2(mE - mF) \cdot CD$

$(BC^* - BD^*) (AC^* - AD^*) = emF \cdot emE \cdot CD^* = CD^* \cdot CD^*$,
because $emF \cdot emE = CD^*$, as deduced above; therefore
 $BC^* - BD^* : CD^* :: CD^* : AC^* - AD^*$. *Q. E. D.*

The same, by Mr. Lowry, Fig. 551.

Let CD , the line bisecting the vertical angle ACB of the triangle ABC , meet the base AB in D . Make AG, AE , each equal to AD , and BH, BF each equal to DB , and let DG, DH, DE , and DF be joined. Then $\angle AGD = \angle ADG = \frac{1}{2}\angle BAC$; therefore the $\angle CDG$ is half the supplement of the $\angle ABF$, that is, (because $\angle BDF = \angle DFB$) $= \angle DFC$; therefore the $\triangle s GDC, DCF$ are similar. In the same way it is shewn that the $\triangle s HDC, DCE$ are similar. Therefore
 $GC : DC :: DC : CF$, and $EC : DC :: DC : CH$, and compoundedly,
 $GC \cdot EC : DC^* :: DC^* : CF \cdot CH$; but
 $GC \cdot EC = AC^* - AD^*$, and $CF \cdot CH = CB^* - DB^*$; therefore
 $AC^* - AD^* : DC^* :: DC^* : CB^* - DB^*$. *Q. E. D.*

The same by Tyro Philomatheticus, Hull. Fig. 552.

Make $AF = AD$ and \perp to CF , and $BE = BD$ and \perp to CE ; then, CD being the line bisecting the vertical \angle , CF will be $=$ to $AC^* - AD^*$, and $CE^* = BC^* - BD^*$.

Now by Simpson's Geom. B. IV. Prop. 16 and 18, the $\triangle s AFC$ and BEC are similar, whence $\angle ECD = \angle FCD$; again $\angle CED =$ a right-angle (CEB) $+ \angle BED$; but $\angle BED = \angle BDE = \angle EDC + \angle CDB$, and the $\angle AFD = \angle ADF =$ a right angle (AFG) $- \angle DFG$; therefore the $\angle FDC =$ a right-angle $+ \angle DFG$, and the $\angle CDF = \angle FDC + \angle CDB$; Now since the angles ECD and DCF are equal, the $\angle CED + \angle EDC = \angle CDF + \angle DFG$, that is, a rt. $\angle + \angle CDB + \angle EDC + \angle EDC =$ a rt. $\angle + \angle CDB + \angle DFG + \angle DFG$, and taking away the \angle s that are common, we shall have $2\angle EDC = 2\angle DFG$; hence $\angle EDC = \angle DFG$, and the $\triangle s CED, CDF$ are similar, therefore $CF : CD :: CD : CE$, or $CF^* : CD^* :: CD^* : CE^*$. *Q. E. D.*

PROP. XLII. Fig. 553, 554, 555. Pl. 29.

Demonstrated by Mr. James Cunliffe, Fig. 553.

Let FG be a right line intercepted by the tangents, cutting the circle in M and N , and bisected by the chord DE in m .

Draw GH parallel to DE meeting the tangent CF in H , and

to S, the centre of the circle, draw the radius DS; also draw the rest of the lines as in the figure.

Because mD and GH are parallel, and $Fm = mG$, it is plain that $FD = DH$: but SD is \perp to DF , by Euc. 18, III; therefore $SF = SH = SG$; consequently the triangle FSG is isosceles. Now the line Sm , which bisects FG will be perpendicular thereto, as appears from Euc. 12, I; Sm will therefore bisect the chord MN by Euc. 8. III. *Q. E. D.*

The same by Mr. John Lowry, Fig. 554.

Let AB, AC, be two tangents drawn from the point A and touching the circle in B and C, and let EF be also drawn to meet the circle at I and H and the line joining BC at D. Then if FD be \perp to DE, ID will be \perp to DH.

Draw FG parallel to BC and let it meet AC produced in G, and join the centre O with the points E, B, F, G, C and D. Then since $AB = AC$, $AE = AG$, and conseq. $OF = OG$: but $DE = DF$ (by hypothesis); therefore by parallels $EC = CG$, and OC is \perp to EG; therefore $OE = OG = OF$, and conseq. OD is \perp to EF, and therefore DI is \perp to DH.

Conversely. If DI be \perp to DH, FD will be \perp to DE.

For DO is \perp to IH, therefore the points B, F, D, O, are in a circle, and so are also the points O, D, E, C; therefore the $\angle DEO = OCD = OBD = OFD$, and $OF = OE$; therefore $ED = DF$. *Q. E. D.*

The same by Tyro Philomatheticus. Fig. 555.

The $\angle AFE$ being \perp BFD, and $EAF = BFD + BDE$, we have by Prop. XL. $FE : EA :: FD : DB$, but $FE = FED$, therefore $EA = DB$, and by Simpson's Geometry III. 32, the rectangle $GEH = EA^*$, and $HDG = DB^*$; whence $GE = HD$, and $GF = FH$.

Conversely. By Prop. XL, $FE : EA :: FD : DB$, $FE^* : EA^* :: FD^* : DB^*$, but $EA^* =$ rectangle GEH , and $DB^* = HDG$, therefore $FE^* : GEH :: FD^* : HDG$, and by division $FE^* - GEH : GEH :: FD^* - HDG : HDG$; that is, $GF^* : GEH :: HF^* : HDG$, but $GF = HF$; hence $GEH = HDG$, or $EA = DB$, and conseq. $FE = FD$. *Q. E. D.*

PROP.

PROP. XLIII. Fig. 556. Pl. 29.

Demonstrated by Meffrs. Cunliffe, Lowry, and Tyro Philomatheticus.

Let ACD be a \triangle having its sides AC , DC , equal to each other.

Draw DE and $Cm \perp$ to the sides AC and AD respectively. It appears from Euc. 12. I. that AD is bisected in m . And because DmC and DEC are right angles, the points D , m , E , C are in the circumference of the same circle, therefore by Euc. 36, III. $AC \cdot AE = AD \cdot Am = AD \cdot \frac{1}{2}AD = \frac{1}{2}AD^2$. *Q. E. D.*

PROP. XLIV. Fig. 557, Pl. 29.

Demonstrated by Meffrs. Cunliffe, Lowry, and Tyro Philomatheticus.

$$\begin{aligned} \text{First. } (AB+AD) \cdot BC + BC^2 &= AB \cdot BC + AD \cdot BC + BC^2 \\ &= AB \cdot BC + (AD+BC) \cdot BC \\ &= AB \cdot BC + (AB+CD) \cdot BC \\ &= AB \cdot BC + AB \cdot BC + CD \cdot BC \\ &= 2AB \cdot BC + CD \cdot BC. \quad Q. E. D. \end{aligned}$$

$$\begin{aligned} \text{Secondly. } (AB+AD) \cdot CD + CD^2 &= (2AD+DB) \cdot CD + CD^2 \\ &= 2AD \cdot CD + DB \cdot CD + CD^2 \\ &= 2AD \cdot CD + (DB+CD) \cdot CD \\ &= 2AD \cdot CD + BC \cdot CD. \quad Q. E. D. \end{aligned}$$

PROP. XLV. Fig. 558, 559, Pl. 29.

Demonstrated by Mr. John Lowry.

Let ABC be a \triangle , and let CD , CE be drawn to make the \angle s ACD , ECB equal. Through the points D , E , C , describe a circle to meet AC , CB in F and G , and join FG . Then because the \angle s FCD , ECB are equal, the arcs FD , GF are also equal, therefore FG is parallel to AB . Wherefore

$$\begin{aligned} AC : BC &:: AF : BG, \text{ or} \\ AC \cdot BC &:: AC \cdot AF = AD \cdot AE : BC \cdot BG = BE \cdot BD. \quad Q. E. D. \end{aligned}$$

PROP. XLVI. Fig. 560, 561, 562, 563, 564. Pl. 29.

Demonstrated by Mr. James Cunliffe, Fig. 560, 561.

First. When the point C is without the circle.

Draw AD , upon which produced let fall the \perp CF and join BD . The $\angle ADB$ in a semi-circle is a right angle, by Euc. 31, III. wherefore the triangles AED and ADB are similar; therefore $AE : AD :: AD : AB$, whence by Euc. 17, VI.

$AD^2 = AE \cdot AB$. And because CFD and CED are right angles, the points C , E , D , F , lie in the circumference of a circle as appears from Euc. 22, III; therefore by Euc. 36, III.

$$AC \cdot AE = AF \cdot AD : \text{but}$$

$$AC \cdot AE = (AB + BC) \cdot AE = AB \cdot AE + BC \cdot AE = AD^2 + BC \cdot AE, \text{ and}$$

$$AF \cdot AD = (AD + DF) \cdot AD = AD^2 + AD \cdot DF; \text{ therefore } AD^2 + BC \cdot AE = AD^2 + AD \cdot DF, \text{ and}$$

by taking away the common square AD^2 from each, there will remain

$$BC \cdot AE = AD \cdot DF : \text{but from what is just deduced,}$$

$$AC \cdot AE = AD^2 + AD \cdot DF, \text{ whence by addition}$$

$$AC \cdot AE + BC \cdot AE = AD^2 + 2AD \cdot DF, \text{ or}$$

$$(AC + BC) \cdot AE = AD^2 + 2AD \cdot DF; \therefore \text{by Euc. 12, II.}$$

$$AC^2 = DC^2 + AD^2 + 2AD \cdot DF = DC^2 + (AC^2 + BC^2) \cdot AE.$$

Q. E. D.

Secondly. When the point C is within the circle.

The triangles AED and ADB are similar, therefore

$$AE : AD :: AD : AB; \text{ whence}$$

$$AD^2 = AB \cdot AE = (AC + BC) \cdot AE = AC \cdot AE + BC \cdot AE, \text{ and}$$

$$AD \cdot AF = AC \cdot AE; \text{ therefore}$$

$$AD^2 - AD \cdot AF = (AD - AF) \cdot AD$$

$$= AD \cdot DF = BC \cdot AE, \text{ or}$$

$$2AD \cdot DF = 2BC \cdot AE: \text{ but}$$

$$AD^2 = AC \cdot AE + BC \cdot AE, \text{ as deduced above. Whence}$$

$$AD^2 - 2AD \cdot DF = AC \cdot AE - BC \cdot AE$$

$$= (AC - BC) \cdot AE, \text{ and theref. Euc. 13, II.}$$

$$AC^2 = DC^2 + AD^2 - 2AD \cdot DF = DC^2 + (AC - BC) \cdot AE.$$

Q. E. D.

The same by Mr. John Lowry. Fig. 562, 563.

$$AC^2 = CE^2 + AE^2 + 2CE \cdot EA; \text{ but}$$

$$AE^2 + 2CE \cdot AE = (AE + 2CE) \cdot AE = (AC + CB + BE) \cdot AE, \text{ fig. 562}$$

$$\text{or} = (AC - CB + BE) \cdot AE, \text{ fig. 563.}$$

$$\text{Also } CD^2 = CE^2 + ED^2, \text{ and } ED^2 = BE \cdot EA;$$

$$\text{Therefore } CD^2 = CE^2 + BE \cdot EA;$$

$$\text{Consequently } AC^2 = CD^2 + (AC \pm CB) \cdot AE.$$

Q. E. D.

The

The same by Tyro Philomatheticus. Fig. 564.

It is evident that

$$AC^* (=CE^* + AC^* - CE^*) = CE^* + (AC - CE) \cdot (AC + CE);$$

now when C is in the diameter produced

$$AC - CE = AE, \text{ and } AC + CE = AC + CB + EB; \text{ whence}$$

$$AC^* = CE^* + (AC + CB + EB) \cdot AE$$

$$= CE^* + AE \cdot EB + AE \cdot (AC + CB)$$

$$= CD^* + AE \cdot (AC \cdot CB);$$

and when C is in the diameter itself,

$$AC + CE = AE, \text{ and } AC - CE = AC - CB + EB; \text{ therefore}$$

$$AC^* = CE^* + AE \cdot (AC - CB + EB)$$

$$= CE^* + AE \cdot EB + AE \cdot (AC - CB)$$

$$= CD^* + AE \cdot (AC - CB).$$

Q. E. D.

ARTICLE XII.

Demonstration that the Area of a Parabolic Segment contained under the Abscissa, the ordinate and the curve is equal to two-thirds of the parallelogram contained under the abscissa and ordinate. By WILLIAM FREND, Esq. Fellow of Jesus College, Cambridge.

LET ABC (Fig. 578, Plate 29.) be a segment of a parabola under the abscissa AB, ordinate BC, and curve AC. Through C draw CD parallel to AB, and through A draw AD parallel to BC. Then the two turvilinear areas ABC, ACD, make up the whole parallelogram ABCD; and if p and q are certain fractional numbers

$$ABC = \frac{ABCD}{p} \text{ and } ACD = \frac{ABCD}{q}$$

Let the lines AB, AD, be produced to E and I, and through G draw GI parallel to AE and meeting BC produced in H. And join C, G.

Then when the abscissa AB is increased by the magnitude BE and the ordinate BC by the magnitude FG, the area ABC is increased by the mixtilineal area BEGC, and in the same manner the area ACD is increased by the mixtilineal area DCGI. Let the area intercepted between the chord CG and the arc CG be called v ; the line AB = x , the ordinate BC = y , the increment of AB = m = BE and the increment of BC = n = FG.

Then

Then the mixtilineal area $BCGE = ym + \frac{mn}{2} + v$,

and the mixtilineal area $DCGI = xn + \frac{mn}{2} - v$.

Let the parameter $= 2a$,

therefore $y^* = 2ax$ and $x = \frac{y^*}{2a}$,

and $(y + n)^* = 2a \times (x + m)$;
therefore $y^* + 2yn + n^* = 2ax + 2am$,

or $2yn + n^* = 2am$

and $\frac{yn}{a} + \frac{n^*}{2a} = m$.

Therefore $ym = \frac{y^*n}{a} + \frac{yn^*}{2a}$

and $\frac{mn}{2} = \frac{yn^*}{2a} + \frac{n^3}{4a}$;

Therefore $ym + \frac{mn}{2} + v = \frac{y^*n}{a} + \frac{yn^*}{2a} + \frac{n^3}{4a} + v = BCGE$

and $xn + \frac{mn}{2} - v = \frac{y^*n}{2a} + \frac{yn^*}{2a} + \frac{n^3}{4a} - v = DCGI$.

Now $\frac{AEGI}{p} - \frac{ABCD}{p} = \frac{(x + m)(y + n)}{p} - \frac{xy}{p}$
 $= \frac{(y + n)^*}{2a} \times \frac{y + n}{p} - \frac{y^*}{2a} \times \frac{y}{p}$
 $= \frac{(y + n)^3}{2ap} - \frac{y^3}{2ap}$
 $= \frac{3y^*n}{2ap} + \frac{3yn^*}{2ap} + \frac{n^3}{2ap} = A$

Make $A = BCGE$;

Therefore $\frac{y^*n}{a} + \frac{yn^*}{a} + \frac{n^3}{4a} + v = \frac{3y^*n}{2ap} + \frac{3yn^*}{2ap} + \frac{n^3}{2ap}$;

now if it is true that the parabolic area AEG is equal to $\frac{AEGI}{p}$,
then since it will be true whatever is the magnitude of m , the ho-
mologous terms on each side of the equation will be equal to each
other*.

* See Preface to my Principles of Algebra, or the true Theory of Equations established on Mathematical Demonstration. Part the Second, page xii.

Namely

Namely $\frac{y^n}{a} = \frac{3y^n}{2ap}$, or $p = \frac{3}{2}$.

$\frac{y^n}{a} = \frac{3y^n}{2aq}$, or $q = 3$,

$$\frac{n^3}{4a} + v = \frac{n^3}{2ap} = \frac{n^3}{3a};$$

$$\text{Therefore } v = \frac{n^3}{3a} - \frac{n^3}{4a} = \frac{n^3}{12a}.$$

$$\text{Also } \frac{\text{AEGI}}{q} - \frac{\text{ABCD}}{q} = \frac{3y^n}{2aq} + \frac{3y^n}{2aq} + \frac{n^3}{2aq} = B.$$

Make $B = \text{DCGI}$.

$$\text{Therefore } \frac{y^n}{2a} + \frac{y^n}{2a} + \frac{n^3}{4a} - v = \frac{3y^n}{2aq} + \frac{3y^n}{2aq} + \frac{n^3}{2aq}.$$

Now if it is true that the area ACGI is equal to $\frac{\text{AEGI}}{q}$, then since it will be true whatever is the magnitude of n the homologous terms on each side of the equation will be equal to each other*.

Namely $\frac{y^n}{2a} = \frac{3y^n}{2aq}$, or $q = 3$

$\frac{y^n}{2a} = \frac{3y^n}{2aq}$, or $q = 3$

$$\frac{n^3}{4a} - v = \frac{n^3}{2aq} = \frac{n^3}{6a};$$

$$\text{Therefore } v = \frac{n^3}{4a} - \frac{n^3}{6a} = \frac{n^3}{12a} \text{ as before.}$$

Thus the numbers p and q are determined; namely p to be $\frac{3}{2}$ and q to be 3, consequently the area ABC = $\frac{2}{3}$ ABCD, and the area ACD = $\frac{1}{3}$ ABCD.

Cor. The area contained between the chord of a parabola and the arc of the parabola may always be found. And if the chord is drawn from the vertex of the parabola this area is equal to the square of the ordinate multiplied into the number, found by dividing the ordinate by twelve times the semi-parameter.

*. See the preceding Note.

ARTICLE XIII.

Improved Solutions to some curious Mathematical Problems.

(Continued from Page 10.)

PROB. III. *By Mr. JAMES CUNLIFFE.*

TO find three positive integers, such, that the difference of every two of them may be a square number; and also that the difference between the sum of every two of them and the third may be a square number?

SOLUTION.

Denote the required integers by x , y , and z ; and by the question, put $x + y - z = a^2$, $x + z - y = b^2$, and $y + z - x = c^2$. Half the sum of the first and second of these is $\left\{ x = \frac{1}{2}(a^2 + b^2) \right.$;

Half the sum of the first and third is $y = \frac{1}{2}(a^2 + c^2)$;
And half the sum of the second and third is $z = \frac{1}{2}(b^2 + c^2)$.

From whence $x - y = \frac{1}{2}(b^2 - c^2)$, $a - z = \frac{1}{2}(a^2 - c^2)$, and $y - z = \frac{1}{2}(a^2 - b^2)$; which three expressions must all be square numbers by the question; in order to effect this, put

$x - y = \frac{1}{2}(b^2 - c^2) = e^2$, and $x - z = \frac{1}{2}(a^2 - c^2) = d^2$; from whence $y - z = \frac{1}{2}(a^2 - b^2) = d^2 - e^2 = a$ square by the question.

From the last expression $a^2 - b^2 = 2(d^2 - e^2)$, which may be divided into factors thus $(a + b)(a - b) = \frac{2s}{r}(d + e) \times \frac{r}{s}(d - e)$.

Put $a + b = \frac{2s}{r}(d + e)$, then will $a - b = \frac{r}{s}(d - e)$;

from which two equations we have

$$a = \frac{s}{r}(d + e) + \frac{r}{2s}(d - e) = \frac{d(2s^2 + r^2) + e(2s^2 - r^2)}{2rs}, \text{ and}$$

$$b = \frac{s}{r}(d + e) - \frac{r}{2s}(d - e) = \frac{d(2s^2 - r^2) + e(2s^2 + r^2)}{2rs}.$$

But $d^2 - e^2$ must be a square as observed above, and it is well known that this will be the case when

$d = 2rs(m^2 + n^2)$, and $e = 2rs \times 2mn$, these being substituted for d and e in the above expressions for a and b they become

$$a = (m^2 + n^2)(2s^2 + r^2) + 2mn(2s^2 - r^2), \text{ and}$$

$$b = (m^2 + n^2)(2s^2 - r^2) + 2mn(2s^2 + r^2). \text{ Now, by means of these and the preceding part of the solution}$$

$$\begin{aligned}
 c^2 - b^2 - 2c^2 &= \left\{ (m^2 + n^2)(2s^2 - r^2) + 2mn(2s^2 + r^2) \right\}^2 - 32r^2s^2m^2n^2 \\
 &= \left\{ (m^2 + n^2)^2(2s^2 - r^2)^2 + 4mn(m^2 + n^2)(4s^4 - r^4) \right. \\
 &\quad \left. + 4m^2n^2(2s^2 + r^2)^2 - 32r^2s^2m^2n^2 \right\} \\
 &= \left\{ (m^2 + n^2)^2(2s^2 - r^2)^2 + 4mn(m^2 + n^2)(4s^4 - r^4) \right. \\
 &\quad \left. + 4m^2n^2(2s^2 + r^2)^2 \right\}.
 \end{aligned}$$

Dividing by $(2s^2 - r^2)^2$ there will be had

$$\begin{aligned}
 \frac{c^2}{(2s^2 - r^2)^2} &= (m^2 + n^2)^2 + 4mn(m^2 + n^2) \left(\frac{2s^2 + r^2}{2s^2 - r^2} \right) + 4m^2n^2 \\
 &= m^4 + 4qmn^2n + 6m^2n^2 + 4qmn^2 + n^4, \text{ by putting } q = \frac{2s^2 + r^2}{2s^2 - r^2}
 \end{aligned}$$

Assume $m^2 + 2qmn - n^2 = c \div (2s^2 - r^2)$, then will

$$\begin{aligned}
 \frac{c^2}{(2s^2 - r^2)^2} &= (m^2 + 2qmn - n^2)^2 \\
 &= m^4 + 4qmn^2n + 4q^2m^2n^2 - 2m^2n^2 - 4qmn^3 + n^4 \\
 &= m^4 + 4qmn^2n + 6m^2n^2 + 4qmn^3 + n^4.
 \end{aligned}$$

Whence $4qmn^2n - 2m^2n^2 - 4qmn^3 = 6m^2n^2 + 4qmn^3$,
or $m^2n^2(4q^2 - 8) = 8qmn^3$; Dividing by $4mn^2$

$$m(q^2 - 2) = n(2q), \text{ or } \frac{m}{n} = \frac{2q}{q^2 - 2} = \frac{2(4s^4 - r^4)}{12s^2r^2 - 4s^4 - r^4}.$$

Whence it appears that m and n may be denoted by any two numbers in the ratio of $2(4s^4 - r^4)$ and $12s^2r^2 - 4s^4 - r^4$ respectively, and r and s taken at pleasure.

$$\begin{aligned}
 \text{Now } \frac{c}{2s^2 - r^2} &= m^2 + 2qmn - n^2 = m^2 - n^2 + 2 \left(\frac{2s^2 + r^2}{2s^2 - r^2} \right) mn, \text{ as} \\
 \text{assumed above, whence } c &= (m^2 - n^2)(2s^2 - r^2) + 2mn(2s^2 + r^2).
 \end{aligned}$$

Example. If r and s be taken each $= 1$, then m and n will be found to be in the ratio of 6 to 7, or we may put $m = 6$, and $n = 7$:

$$\begin{aligned}
 a &= (m^2 + n^2)(2s^2 + r^2) + 2mn(2s^2 - r^2) = 339, \\
 b &= (m^2 + n^2)(2s^2 - r^2) + 2mn(2s^2 + r^2) = 387, \text{ and} \\
 c &= (m^2 - n^2)(2s^2 - r^2) + 2mn(2s^2 + r^2) = 239.
 \end{aligned}$$

Whence $x = \frac{1}{2}(a^2 + b^2) = 114245$, $y = \frac{1}{2}(a^2 + c^2) = 86021$, and $z = \frac{1}{2}(b^2 + c^2) = 85345$, which are three numbers that will answer the conditions of the question.

PROB. IV. By Mr. JAMES CUNLIFFE.

To find three square whole numbers, such, that the difference between the sum of every two of them, and the third may be a square number.

SOLUTION

SOLUTION.

Let the required squares be denoted by x^2 , y^2 , and z^2 , and by the question, put

$$x^2 + y^2 - z^2 = a^2, \quad x^2 + z^2 - y^2 = b^2, \quad \text{and} \quad y^2 + z^2 - x^2 = c^2.$$

The sum of the three equations is $x^2 + y^2 + z^2 = a^2 + b^2 + c^2$, and by taking half the difference between this and each of the former equations there will be had

$$x^2 = \frac{1}{2}(a^2 + b^2), \quad y^2 = \frac{1}{2}(a^2 + c^2), \quad \text{and} \quad z^2 = \frac{1}{2}(b^2 + c^2);$$

from the two first of these $a^2 = 2x^2 - b^2 = 2y^2 - c^2$.

Put $x = y + rv$, and $b = c + sv$, then

$$\begin{aligned} 2x^2 - b^2 &= 2(y + rv)^2 - (c + sv)^2 \\ &= 2y^2 - c^2 + 4ryv + 2r^2v^2 - 2cv - s^2v^2 = 2y^2 - c^2. \end{aligned}$$

Whence $v = (2sc - 4ry) \div (2r^2 - s^2)$;

$$\text{therefore } x = y + rv = \left\{ 2rs - y(2r^2 + s^2) \right\} \div (2r^2 - s^2),$$

$$\text{and } b = c + sv = \left\{ c(2r^2 + s^2) - 4rsy \right\} \div (2r^2 - s^2).$$

Now from what is done $2y^2 - c^2 = a^2$, and therefore that y , c , and a may be rational, put $(2r^2 - s^2)(m^2 + n^2) = y$,

$$(2r^2 - s^2)(n^2 - m^2 + 2mn) = c, \text{ and } (2r^2 - s^2)(m^2 - n^2 + 2mn) = a.$$

The reason of these last assumptions will perhaps appear plainer by observing that a , y , and c are the roots of three squares in arithmetical progression. By means of which, and what is before deduced

$$x = 2rs(m^2 - n^2 + 2mn) - (2r^2 + s^2)(m^2 + n^2), \text{ and}$$

$$b = (2r^2 + s^2)(n^2 - m^2 + 2mn) - 4rs(m^2 + n^2): \text{ therefore}$$

$$z^2 = \frac{1}{2}(b^2 + c^2) = \left\{ \frac{(4r^4 + s^4)(m^2 - n^2 + 2mn)^2 + 4rs(2r^2 + s^2)(m^2 - n^2)}{-8rsmn(2r^2 + s^2)(m^2 + n^2) + 8r^2s^2(m^2 + n^2)^2} \right\}$$

$$= \left\{ \frac{m^4(2r^2 + 2rs + s^2)^2 - 4m^3n(4r^4 + 4r^2s + 2rs^2 + s^4)}{+ 2m^2n^2(4r^4 + 8r^2s^2 + s^4) + 4mn^3(4r^4 - 4r^2s - 2rs^2 + s^4)} \right. \\ \left. + n^4(2r^2 - 2rs + s^2)^2 \right\}.$$

$$\text{Assume } \left\{ \frac{m^2(2r^2 + 2rs + s^2)}{-2mn\left(\frac{4r^4 + 4r^2s + 2rs^2 + s^4}{2r^2 + 2rs + s^2}\right)} \right\} = z, \text{ then will}$$

$$-n^2(2r^2 + 2rs + s^2)$$

$$z^2 = \left\{ \frac{m^4(2r^2 + 2rs + s^2)^2 - 4m^3n(4r^4 + 4r^2s + 2rs^2 + s^4)}{+ 2m^2n^2(4r^4 + 8r^2s^2 + s^4) + 4mn^3(4r^4 - 4r^2s - 2rs^2 + s^4) + n^4(2r^2 - 2rs + s^2)^2} \right\}.$$

$$= \left\{ \begin{array}{l} m^4 (2r^2 + 2rs + s^2)^2 - 4m^3 n (4r^4 + 4r^3s + 2rs^2 + s^4) \\ + 4m^2 n^2 \left(\frac{4r^4 + 4r^3s + 2rs^2 + s^4}{2r^2 + 2rs + s^2} \right)^2 \\ - 2m^2 n^2 (4r^4 + s^4) \\ + 4mn^3 (4r^4 + 4r^3s + 2rs^2 + s^4) \left(\frac{2r^2 - 2rs + s^2}{2r^2 + 2rs + s^2} \right) \\ + n^4 (2r^2 - 2rs + s^2)^2. \end{array} \right.$$

This being reduced gives

$$m = n \times \frac{(4r^4 + s^4)(4r^4 + 4r^3s - 2rs^2 + s^4) - (2r^2 + 2rs + s^2)(4r^4 - 4r^3s - 2r^2s + s^4)}{(2r^2 + s^2)^2 (2r^2 + 2rs + s^2)^2 - (4r^4 + 4r^3s + 2rs^2 + s^4)^2},$$

which may be farther reduced to

$$m = n \times \frac{4r^3s + 4r^2s^2 + 2rs^3}{4r^4 + 4r^3s + 2r^2s^2 + 2rs^3 + s^4},$$

$$\text{or } \frac{m}{n} = \frac{4r^3s + 4r^2s^2 + 2rs^3}{4r^4 + 4r^3s + 2r^2s^2 + 2rs^3 + s^4}.$$

Hence it appears that m and n may be expounded by any two numbers in the ratio of $4r^3s + 4r^2s^2 + 2rs^3$ and $4r^4 + 4r^3s + 2r^2s^2 + 2rs^3 + s^4$ respectively, and r and s taken at pleasure.

Example 1. Suppose r and s each = 1, then $\frac{m}{n} = \frac{10}{13}$, whence

we may take $m = 10$ and $n = 13$, by means of which,
 $x = 2rs (n^2 - m^2 + 2mn) = (2r^2 + s^2)(m^2 + n^2) = 149$
 $y = (2r^2 - s^2)(m^2 + n^2) = 269$, and

$$z = m^2(2r^2 + 2rs + s^2) - 2mn \left(\frac{4r^4 + 4r^3s + 2rs^2 + s^4}{2r^2 + 2rs + s^2} \right) - n^2 (2r^2 - 2rs + s^2) = -241.$$

or 149, 269, and 241 are the roots of three squares that will answer.

Example 2. If $r = 1$ and $s = -1$, then $\frac{m}{n} = \frac{-2}{1}$, or $m = -2$ and $n = 1$; whence $x = -1$, $y = 5$, and $z = -5$, or the roots of the squares may be 1, 5 and 5, but as two of them are equal they deserve little notice.

I shall now shew how the expressions for x and y might have been obtained by the method of factors.

It was found that $a^2 = \frac{1}{2}(ex^2 - b^2) = \frac{1}{2}(2y^2 - c^2)$, whence $x^2 - y^2 = \frac{1}{2}(b^2 - c^2)$; this expression may be divided into factors

$$\text{thus } (x + y)(x - y) = \frac{r}{2s}(b + c) \times \frac{s}{r}(b - c);$$

put $x + y = \frac{r}{2s}(b + c)$, then will $x - y = \frac{s}{r}(b - c)$; whence

$$x = \frac{r}{4s}(b+c) + \frac{s}{2r}(b-c) = \frac{r^2(b+c) + 2s^2(b-c)}{4rs}$$

$$= \frac{b(2s^2 + r^2) - c(2s^2 - r^2)}{4rs}, \text{ and}$$

$$y = \frac{r}{4s}(b+c) - \frac{s}{2r}(b-c) = \frac{r^2(b+c) - 2s^2(b-c)}{4rs}$$

$$= \frac{c(2s^2 + r^2) - b(2s^2 - r^2)}{4rs}, \text{ and}$$

from the last of these $b = \frac{c(2s^2 + r^2) - 4rsy}{2s^2 - r^2}$.

But $y^2 = \frac{1}{2}(a^2 + c^2)$ or $2y^2 = a^2 + c^2$, that is a^2, y^2 , and c^2 , are three squares in arithmetical progression; therefore we may put

$$(2s^2 - r^2)(m^2 - n^2 + 2mn) = a, (2s^2 - r^2)(m^2 + n^2) = y, \text{ and}$$

$$(2s^2 - r^2)(n^2 - m^2 + 2mn) = c; \text{ by means of which}$$

$$b = \frac{c(2s^2 + r^2) - 4rsy}{2s^2 - r^2} = (2s^2 + r^2)(n^2 - m^2 + 2mn) - 4rs(m^2 + n^2), \text{ and}$$

$$x = \frac{b(2s^2 + r^2) - c(2s^2 - r^2)}{4rs} = 2rs(n^2 - m^2 + 2mn) - (2s^2 + r^2)(m^2 + n^2),$$

which are the same expressions as were found the other way.

An answer to the preceding question may be seen in the Gentleman's Diary for 1802, which differs from that here given only in this, yiz. in the Diary, the values of x, y , and z , are deduced from those of a, b , and c , previously obtained, which is not necessary in the calculation.

PROB. V. By Mr. JAMES CUNLIFFE.

To find the value of x so that $x^2 + ax$, $x^2 + bx$, and $x^2 + cx$ may be all rational squares.

SOLUTION.

Assume $n - x$ for the root of the first; that is, make

$$x^2 + ax = (n - x)^2 = n^2 - 2nx + x^2, \text{ from whence } x = n^2 \frac{n^2}{2n + a};$$

this being written for x in the second condition gives,

$$x^2 + bx = \frac{n^4}{(2n + a)^2} + \frac{bn^2}{2n + a} = \frac{n^2}{(2n + a)^2} \times \left\{ n^2 + b(2n + a) \right\} =$$

a square; therefore $n^2 + b(2n + a)$ = a square

Assume $s - n$ for the root of this square, and then

$$s^2 + b(2n+a) = (s-n)^2 = s^2 - 2sn + n^2, \text{ whence } n = \frac{s^2 - ab}{2(b+s)},$$

and $x = \frac{n^2}{2n+a} = \frac{(s^2 - ab)^2(b+s)}{4(b+s)(s^2 + sa)} = \frac{(s^2 - ab)^2}{4s(a+s)(b+s)};$ and this being substituted for x in the third and last condition gives

$$x^2 + cx = \frac{(s^2 - ab)^4}{16s^2(a+s)^2(b+s)^2} + \frac{c(s^2 - ab)^2}{4s(a+s)(b+s)}$$

$$= \frac{(s^2 - ab)^2}{16s^2(a+s)^2(b+s)^2} \times \left\{ (s^2 - ab)^2 + 4cs(a+s)(b+s) \right\} =$$

a square;

$$\text{therefore } \left. \begin{array}{l} (s^2 - ab)^2 + 4cs(a+s)(b+s) \\ \hline \end{array} \right\} = \left\{ \begin{array}{l} a^2b^2 + 4sabc + 2s^2 \left\{ 2c(b+a) - ab \right\} \\ + 4cs^3 + s^4 = \text{a square.} \end{array} \right\}$$

Assume $ab + 2cs - s^2$ for the root of the last square, then will

$$a^2b^2 + 4sabc + 2s^2 \left\{ 2c(b+a) - ab \right\} = (ab + 2cs - s^2)^2$$

$$+ 4cs^3 + s^4 \qquad \qquad \qquad \left. \right\} = \left\{ \begin{array}{l} a^2b^2 + 4sabc + 4c^2s^2 \\ - 2abs^2 - 4cs^3 + s^4; \end{array} \right\}$$

Whence $2s^2 \times 2c(b+a) + 4cs^3 = 4c^2s^2 - 4cs^3$, and by transposition $8cs^3 = 4c^2s^2 - 4cs^2(b+a)$; whence $s = \frac{1}{2} \left\{ c - (b+a) \right\}$, and by means of this

$$x = \frac{(s^2 - ab)^2}{4s^2(a+s)(b+s)} = \frac{\left\{ [c - (a+b)]^2 - 4ab \right\}^2}{8 \left\{ c - (a+b) \right\} \times (c+a-b) \times (c+b-a)}.$$

PROB. VI. By Mr. JAMES CUNLIFFE.

To find three square numbers such, that their sum being severally added to their three sides shall make square numbers.

SOLUTION.

In the first place it may be observed that 4, 9, and 36 are three square numbers, whose sum is a square, viz. 49; wherefore let the required squares be denoted by $4x^2$, $9x^2$ and $36x^2$. Now the sum of these being severally added to their three sides gives, $49x^2 + 2x$, $49x^2 + 3x$, and $49x^2 + 6x$, which expressions are all

all to be squares by the question:—or dividing by 49 which is a square number, there will be had

$x^2 + \frac{2x}{49}$, $x^2 + \frac{3x}{49}$, and $x^2 + \frac{6x}{49}$, and these must consequently be all squares.

The question now adapts itself to the general form, in the preceding problem, therefore we may put $a = \frac{2}{49}$, $b = \frac{3}{49}$, and $c = \frac{6}{49}$; whence, and by means of what has been done,

$$x = \frac{\{[c - (a+b)]^2 - 4ab\}}{8 \{c - (a+b)\} \times (c+a-b) \times (c+b-a)} = \frac{529}{13720};$$

and therefore the roots of the three squares will be

$$2x = \frac{1058}{13720}, \quad 3x = \frac{1587}{13720}, \quad \text{and } 6x = \frac{3174}{13720}.$$

* * * This is No. 22 of Mr. Bonnycastle's collection of Diophantine Problems.

PROB. VII. By Mr. JAMES CUNLIFFE.

To find three square numbers in arithmetical progression, such that if each be added to its respective root, the three sums thence arising shall be rational squares.

SOLUTION.

In the first place $49x^2$, $25x^2$ and x^2 are three squares in arithmetical progression; and each of them being added to its respective root gives

$49x^2 + 7x$, $25x^2 + 5x$, and $x^2 + x$, which three expressions are all to be rational squares by the question.

Let the first and second be divided by 49 and 25 respectively, and there will be had

$x^2 + \frac{x}{7}$, $x^2 + \frac{x}{5}$, and $x^2 + x$, which must consequently be all squares.

This question is now adapted to the general form in Prob. V, and we may put $a = \frac{1}{7}$, $b = \frac{1}{5}$, and $c = 1$, which gives

$$x = \frac{\{[c - (a+b)]^2 - 4ab\}}{8 \{c - (a+b)\} \times (c+a-b) \times (c+b-a)} = \frac{151921}{7863240};$$

Whence

Whence the roots of the three squares are

$$7x = \frac{1059247}{7863240}, 5x = \frac{756605}{7863240}, \text{ and } x = \frac{151321}{7863240}.$$

* * * The preceding question is answered in the fourth number of the Student.

The following question with various others of a similar nature might be answered by a like method of procedure, if any one would be at the trouble of the calculation, *viz.*

To find three square numbers such that the sum of every two shall be a rational square; and if each be added to its respective root, the sums thence arising shall be rational squares.

PROB. VIII. *By Mr. JAMES CUNLIFFE.*

To divide a given number (n) into four such parts, that the difference of every two of them may be a square number.

SOLUTION.

Let the required parts be denoted by x, y, z , and v ,

Then by the question $\begin{cases} x + y + z + v = n \\ x - y = c^2 \\ x - z = b^2 \text{ and} \\ x - v = d^2 \end{cases}$ also $x - y, z - v$, and $y - v$ must be squares.

One-fourth of the sum of the four first gives

$$\begin{aligned} x &= \frac{1}{4}(n + a^2 + b^2 + c^2), \text{ and from the second} \\ y &= x - c^2 = \frac{1}{4}(n + a^2 + b^2 - 3c^2), \text{ and from the third} \\ z &= x - b^2 = \frac{1}{4}(n + a^2 + c^2 - 3b^2), \text{ and from the fourth} \\ v &= x - a^2 = \frac{1}{4}(n + b^2 + c^2 - 3a^2). \text{ And by means of these} \\ z - y &= b^2 - c^2 = \text{a square} \\ z - v &= a^2 - b^2 = \text{a square, and} \\ y - v &= d^2 - c^2 = \text{a square.} \end{aligned}$$

From whence it appears that the relation of the three squares a^2, b^2 , and c^2 must be such, as will make the difference of every two of them a rational square; a^2 being the greatest, and c^2 the least.

Now in one of the solutions to Prob. 1, it was found that a, b , and c may be respectively denoted by 697, 185, and 153, or we may put

$a^2 = 485809, b^2 = 34225$, and $c^2 = 29409$; whence, and by means of what is done above,

$x =$

$x = \frac{1}{4}(n + a^2 + b^2 + c^2)$, $y = x - c^2 = \frac{1}{4}(n + 449807)$,
 $z = x - b^2 = \frac{1}{4}(n + 406543)$ and $v = x - a^2 = \frac{1}{4}(n - 1399793)$;
 where n may be taken at pleasure.

But the least value of n so as to give x , y , z , and v , all positive integers will be readily found to be 1399797, and from thence

$$x = 485810, y = 462401, z = 451585, \text{ and } v = 1.$$

It is easy to perceive, that as (n) may denote any number whatever, we may from what is done, find four numbers such that the difference of every two of them may be a square, and the sum of all four a square, cube, biquadrate, &c.

PROB. IX. By Mr: JAMES CUNLIFFE.

To find four numbers such, that the sum of every two of them may be a rational square; and also that the sum of all four may be a rational square.

SOLUTION.

Let x , y , z , and v denote the numbers.

Then by the question $x + y = a^2$.

$$x + z = b^2$$

$$x + v = c^2$$

$$y + v = d^2$$

$y + z =$ a square, and

$z + v =$ a square.

The sum of the first and third is $2x + y + v = a^2 + c^2$;
 Half the diff. between this and the fourth is $x = \frac{1}{2}(a^2 + c^2 - d^2)$;
 Whence $y = a^2 - x = \frac{1}{2}(a^2 + d^2 - c^2)$

$$z = b^2 - x = \frac{1}{2} \{ 2b^2 + d^2 - (a^2 + c^2) \}$$

$$\text{and } v = d^2 - y = \frac{1}{2}(d^2 + c^2 - a^2).$$

By means of the preceding expressions,

$$y + z = b^2 + d^2 - c^2 = \text{a square} = e^2; \text{ and}$$

$$z + v = b^2 + d^2 - a^2 = \text{a square} = f^2;$$

These two last give $b^2 + d^2 = c^2 + e^2 = a^2 + f^2$.

From the first part of the solution to the first problem it appears that we may put

$$c = \frac{2rsb - (r^2 - s^2)d}{r^2 + s^2}, \text{ and } a = \frac{(p^2 - q^2)b - 2pqd}{p^2 + q^2},$$

where r , s , p , and q may be expounded by any numbers at pleasure.

The sum of the second and fourth equations gives

$$x + y + z + v = b^2 + d^2 = \text{a square by the question,}$$

Therefore

Therefore we may put $2mn = b$, and $m^2 - n^2 = d$,

$$\text{Whence } c = \frac{2rsb - (r^2 - s^2)d}{r^2 + s^2} = \frac{4rsmn - (r^2 - s^2)(m^2 - n^2)}{r^2 + s^2},$$

$$\text{and } a = \frac{(p^2 - q^2)b - 2pqd}{p^2 + q^2} = \frac{(p^2 - q^2)2mn - 2pq(m^2 - n^2)}{p^2 + q^2},$$

and m and n may be taken at pleasure.

Example. If $m = 2$, $n = 1$, $r = 3$, $s = 2$, $p = 4$, and $q = 1$, then $b = 2mn = 4$, $d = m^2 - n^2 = 3$,

$$c = \frac{4rsmn - (r^2 - s^2)(m^2 - n^2)}{r^2 + s^2} = \frac{33}{13},$$

$$\text{and } a = \frac{(p^2 - q^2)2mn - 2pq(m^2 - n^2)}{p^2 + q^2} = \frac{36}{17}.$$

And reducing these values of b , d , c and a to a common denominator, and omitting it, we may put $b = 4 \times 13 \times 17 = 884$, $d = 3 \times 13 \times 17 = 663$, $c = 33 \times 17 = 561$, and $a = 36 \times 13 = 468$. Or, $a^2 = 219024$, $b^2 = 781456$, $c^2 = 314721$, and $d^2 = 439569$, and by means of these $x = \frac{1}{2}(a^2 + c^2 - d^2) = 47088$, $y = a^2 - x = 171936$, $z = b^2 - x = 734368$, and $v = d^2 - y = 267633$, which are four numbers that will answer the question.

By attending to what has been deduced in the foregoing solution, it will appear that any number whatever, which is capable of being divided into two rational squares, may be divided into four such parts, that the sum of every two of them may be a rational square. And this property of being capable of being divided into two rational squares is a restriction that seems indispensably necessary in the number to be divided, as specified above.

ARTICLE XIV.

*Answers to the Mathematical Questions proposed in ARTICLE LI.
VOL. II.*

I. QUESTION 241, *answered by Mr. G. Buffham, of Clifton.*

Put $4x$ and x for the diameters of each vessel; $c = 10$ ale gallons = 1.631944 cubic feet; $a = (8000 \times 5280 + 12) = 42240012$

42240012 feet ; and $p = 5236$. Since the surface of the liquor must be parallel to the surface of the earth, we have $4x^3 \div a$ and $x^3 \div 4a$ for the heights of two spherical segments, the diameters of whose bases are the same as those of the vessels, the contents of which are easily found to be

$$\left(\frac{64}{a^3} x^6 + \frac{48}{a} x^4 \right) \times p \text{ and } \left(\frac{1}{64a^3} x^6 + \frac{3}{16a} x^4 \right) \times p.$$

Then by the question, we have the following equation

$$\left(\frac{64}{a^3} x^6 + \frac{48}{a} x^4 \right) \times p - \left(\frac{1}{64a^3} x^6 + \frac{3}{16a} x^4 \right) \times p = c, \text{ or}$$

$$x^5 + \frac{68}{91} a^3 x^4 = \frac{64c}{4095p}, \text{ or in numbers}$$

$$x^5 + 1333262260831756x^4 = 3671164938496296232664.$$

From this equation x is found to be equal to 40.7375, the less diameter, and $4x = 162.95$ the greater diameter. Whence the heights of the spherical segments are .00015715 and .00001 nearly, and their contents 1.6386 and .006517 respectively, which being added to 109486.08585 the content of either vessel give 109487.724456 and 109486.092367 cubic feet respectively, the quantity of liquor in the vessel when full.

The same, answered by Mr. John Whitley, of Attercliffe Academy, near Sheffield.

Plate 29, Fig. 565. Let PFBGAEP represent the earth, AB, EF the diameters of the vessels parallel to each other, and intersecting a diameter PG in the points m and n ; then it is evident that the given difference will be represented by the zone

AEFB, which is known to be equal to $(En^2 + Am^2 + \frac{nm^2}{3}) \times \frac{1}{2}mn \times p$, where $p = 3.14159$ &c ; therefore putting 10 ale gallons = 2820 cubic inches = 1.631944 cubic feet = a , PG = d , nm = x , En = y , and Am = z , we shall have this

equation, viz. $(y^2 + z^2 + \frac{x^2}{3}) \times \frac{1}{2}px = a$. Now it is very evident by the nature of the question that x will be an exceeding small part, and $\frac{x^2}{3}$ will be considerably much more so, therefore

the rejecting of $x^2 \times \frac{p}{6}$ will very little affect the value of x , which being done our equation becomes

(3)

$(y^2 + z^2) \times \frac{1}{2}px = a$, or $y^2 + z^2 = \frac{2a}{px}$: but by the quest.

$4 : 1 :: z : y$, or $4^2 : 1^2 :: z^2 : y^2$, and by composition

$17 : 1 :: z^2 + y^2 = \frac{2a}{px} : y^2 = \frac{2a}{17px}$; consequently

$z^2 = \frac{32a}{17px}$. Also by a known property of the circle,

$Pn \times Gn = y^2$, and $Pm \times Gm = z^2$; hence

$Gm - Pm = \sqrt{d^2 - \frac{128a}{17px}}$, and $Gn - Pn = \sqrt{d^2 - \frac{8a}{17px}}$,

and the difference of these is $2mn$, or $2x$; that is,

$$\sqrt{d^2 - \frac{8a}{17px}} - \sqrt{d^2 - \frac{128a}{17px}} = 2x.$$

Hence $x = 10001473$ and the greater diameter = 162.94624 feet and the lesser 40.73656 feet; hence the contents are easily found.

II. QUESTION 242, answered by Mr. Cunliffe.

Plate 29, Fig. 566. Let ABC represent the cone, HEGF one of the hyperbolic sections parallel to the axis CD. Draw LE \parallel to AB and cutting CD in M; then will CM and ME be respectively equal to the principal semi-transverse and semi-conjugate axes of the hyperbola HEG, as appears from the writers on conics.

Now by the question, the double ordinate GH will be equal to the side of a square inscribed in the circle AHBG; and therefore

$$ME = DF = GF = AB \div 2\sqrt{2} = DB \div \sqrt{2}.$$

Now by reason of the parallels DE, FE; $DB : ME = DB \div \sqrt{2} :: \sqrt{2} : 1 :: CD : CM = CD \div \sqrt{2}$; and by art. 129. Vol. I. Simpson's Fluxions, the area of the hyperbolic space HEG bounded by the double ordinate GH is expressed by

$$CD \times FG - CM \times ME \times h. l. \frac{CD + \frac{CM \times FG}{ME}}{CM} =$$

$$\frac{CD \times DB}{\sqrt{2}} - \frac{CD \times DB}{2} \times h. l. (\sqrt{2} + 1) =$$

CD

$$\frac{CD \times DB \sqrt{2}}{2} - \frac{CD \times DB}{2} \times h. l. (\sqrt{2} + 1) = CD \times DB$$

$\times 26642.$

Again, by art. 157. Vol. I. Simpson's Fluxions, the solid content of the ungula HEGB is expressed by

$$HBG \times \frac{CD}{3} - HEG \times \frac{DF}{3} = HBG \times \frac{CD}{3} - HEG \times \frac{DB}{3\sqrt{2}};$$

and four times this being taken from the whole content of the cone leaves

$$\frac{2}{3} \times (DB)^2 \times DC + HEG \times \frac{2DB\sqrt{2}}{3} = DB^2 \times DC \times 91784984$$

for the content of what remains after the four slices are cut off.

In the present case where $DC = 7\frac{1}{2}$ feet and $DB = \frac{13}{12}$, the solid content $DB^2 \times DC \times 91784984 = 8.07899$ cubic feet.

The area of the convex surface of the conical ungula HEGB is expressed by $(CB \div DB) \times$ area of the circular segment HBG as appears by art. 166, Vol. I, Simpson's Fluxions: therefore $(4CB \div DB) \times$ area of the segment HBG will express the convex part of the conical surface taken off by the four slices.

Now the whole convex surface of the cone is expressed by $(CB \div DB) \times$ area of the circle AHBG; from whence deducting the part cut off by the four slices, and there will manifestly remain $(CB \div DB) \times$ area of the square inscribed in the circle AHBG $= (CB \div DB) \times 2DB^2 = 2CB \times DB$.

From whence it appears that what remains of the convex surface of the cone, after the four slices are cut off is geometrically quadable.

Wherefore if to what remains of the convex surface of the cone after the four slices are taken off there is added the area of the square base, $2DB^2$, together with the area of the four hyperbolic spaces, $\frac{1}{4} \times HEG$, there will be had $2CB \times DB + 2DB^2 + 4DB \times CD \times 26642 = 27.4245189$ square feet for the whole superficies of what remains after the slices are taken off.

From what has been deduced we may gather the following curious

THEOREM.

If any right cone is cut by planes parallel to the axis so as just to reduce the base to a plane figure bounded by right lines; then the area of the remainder of the convex surface of the cone will be

VOL. III.

L

geome-

geometrically quadrable, its area being expressed by $(CB \div DB) \times$ the area of the said reduced base.

The same, answered by Mr. Buffham, Clifton, near Newark.

The content of the whole cone is easily found = 15927.912 inches.

Now the content of the piece mentioned in the question is equal to the content of the whole cone, minus four times the content of the unguia HEBG.

By a property of the circle and square $1 : \frac{1}{2}\sqrt{2} :: 26 : 13\sqrt{2}$ = GH the side of the square or base of the solid = LE; and FB = $\frac{1}{2}(AB - LE) = 3.8076118$: and by sim. Δ s, $AB = 26 : DC = 90 :: LE = 13\sqrt{2} : CM = 45\sqrt{2}$; also $EF = 90 - 45\sqrt{2} = 26.3604$.

Since EFB is a right angle, it is evident, from Dr. Hutton's Mensuration, Cor. 6. Prob. XXVI. Sect. 1, Part III, that the transverse and conjugate axes are 127.27927 and 18.384776 respectively, also the area of hyperbolic section GEH = 311.71178, by Prob. VI. Sect. 7, Part III, of the same book, which call A; also denote the area of the circular segment GBH by α .

Then by Page 224 of Hutton ut supra,

$$\frac{\frac{3}{4}h}{D-d} \times (\alpha \times D - A \times d \times \frac{DB}{CD}) = 491.836326, \text{ the content of the slice GEBH,}$$

which being multiplied by 4 and the product taken from the whole cone, or 15927.912, leaves 13960.5667 inches, or 8.079 feet nearly, the content of the part remaining after the 4 slices are taken off.

Again, the superficies of the whole cone = $26 \times 3.1416 \times 90.934 \div 2 = 3713.817297$, and by Prob. XXXII: Sect. 1, Part III, of the above mentioned book, the curve surface of one

$$\text{slice} = \sqrt{\{(4h + D - d) \div (D - d)\}} \times a = 337.3794;$$

this multiplied by 4 gives 1349.5176, which taken from the surface of the whole cone leaves 2364.29969; to this adding four times the area of the hyperbolic section GEH (found above) = 1246.84712 and the area of the square base = $(13\sqrt{2})^2 = 338$, we have 3949.1465 inches, or 27.4846 square feet for the superficies of the part remaining after the four slices are taken off.

Neat and ingenious solutions were also received from Messrs. Francis, Marat, and Whitley.

III. QUESTION 249, *answered by Miss Susan May.*

Plate 29, Fig. 567. Let ACB be the triangle required; AD , BE , and CF the \perp s demitted from the angles on the opposite sides, and which meet in a point, as at G . Join DE , DF , and EF . Then because the points B , F , G , D are in a circle, and also the points C , D , G , E , we have $\angle GBF = GDF$, and $\angle ECG = EDG$: but $\angle GBF = GCE$, therefore $EDG = FDG$; and in like manner it may be shewn that $DEG = GEF$ and $GFE = GFD$.

Now in the $\triangle DEF$ the three sides are given, *viz.* $EF = 9$, $ED = 10$, and $FD = 11$; therefore the three \angle s are found by trigonometry, *viz.* $\angle DFE = 58^\circ 59' 42''$, $\angle EDF = 50^\circ 28' 50''$, and $\angle DEF = 70^\circ 31' 28''$; therefore $\angle ADF = 25^\circ 14' 25''$; $\angle DFA = 119^\circ 29' 52''$, and $\angle DAF = 35^\circ 15' 45''$; hence AD is found $= 16.585$, $BD = 11.724$, and $CD = 9.386$. Consequently $(CD + DB) \times \frac{1}{2}AD = 21.11 \times \frac{16.585}{2} = 175.04$ square chains $= 17\frac{1}{2}$ acres, the content required.

The same, answered by Tyro Philomatheticus, of Hull.

Plate 29, Fig. 568. Let ABC represent the triangular field, AD , BE , and CF the \perp s from the \angle s on the opposite sides, G the point of intersection, and ED , EF , FD the given lines. Before I proceed to the calculation it may be thought necessary to prove (as I have not yet seen it done) that, *The perpendiculars from the angles on the opposite sides bisect the angles of the triangle formed by joining the extremities of those perpendiculars.*—On AB describe a semicircle, then because of the right \angle s AEB and ADB , it will pass through the points E and D ; and AEG , AFG being right angles it is manifest that the points A , F , G , and E are in the circumference of a circle, and the $\angle EFG = EAG$; again BFG , BDG , being right \angle s, it is likewise evident that B , F , G , and D are in the circumference of a circle, and $\angle DFG = DBG$: but the \angle s EAG and DBG , standing on the same segment ED , are equal; therefore $EFG = DFG$; and in a similar manner it is easily proved that $FDG = EDG$, and that $DEG = FEG$.

Now $ED = 9$, $EF = 10$, and $FD = 11$, whence the \angle s by Trig. are found, *viz.* $\angle FED = 70^\circ 32'$, $\angle EDF = 58^\circ 59\frac{1}{2}''$ and $\angle EFD = 50^\circ 28\frac{1}{2}''$ from which, and what is done above, we get $\angle ABC (= \text{comp. of } \frac{1}{2} \angle FED) = 54^\circ 44'$, $\angle CAB (= \text{comp. of }$

of $\frac{1}{2} FDE$) = $60^\circ 30\frac{1}{2}'$, and BCA (= comp. of $\frac{1}{2} EFD$) = $64^\circ 45\frac{3}{4}'$; and by trigonometry, as
 sine of $\angle A : EF :: \cos. \frac{1}{2} FED : AF = 9.3808$, and
 sine of $\angle B : FD :: \cos. \frac{1}{2} EDF : FB = 11.7264$;
 therefore $AB = 21.1069$; again as
 sine of $\angle A : EF :: \cos. \frac{1}{2} EFD : AE = 10.3925$, and
 sine of $\angle C : ED :: \cos. \frac{1}{2} EDF : EC = 8.66015$;
 therefore $AC = 19.05265$; hence the area =
 $AB \times AC \times \frac{1}{2} \sin \angle A = 175.01$ chains nearly, or $17\frac{1}{4}$ acres.

The same, answered by Mr. John Whitley.

Plate 29, Fig. 569. Let ABC represent the piece of ground: from the \angle 's, to the opposite sides, draw the \perp 's AE, BF, CD ; draw also the lines DF, DE, EF , intersecting the \perp 's in n, p, m , respectively. Since AEB and AFB are right \angle 's, the points A, F, E, B are in a circle, and for the same reason the points C, E, D, A are in a circle. Therefore $\angle ABF = AEF$, and $ACD = AEB$: but $\angle ABF = ACD$, because each of these is the complement of the same $\angle A$; therefore $\angle AEF = AED$, and consequently the $\perp AE$ bisects the $\angle FED$. In the same manner it may be proved that the \perp 's EDE , and DFE are respectively bisected by the \perp 's CD and BF .

Having premised this the calculation may be as follows. Put $DE = 9$, $FD = 11$ and $EF = 10$; then by Euc. 8, VI, $FE + ED : FD :: FE : Fn = 110 : 19$, whence $Dn = FD - Fn = 11 - 110 : 19 = 99 : 19$, and by Euc. Geo. 26, II, $En = FE \times ED - Fn \times Dn = 21600 : 19$, or $En = 60\sqrt{6} : 19$.

Also $FE + Fn : En :: FE : EO = 2\sqrt{6} : 19$, whence $nO = En - EO = 22\sqrt{6} : 19$.

Because ADO, AFO are right \angle 's, the points A, F, O, D are in a circle; therefore, Euc. 35, III,

$$An \times nO = Fn \times nD, \text{ or } An = \frac{Fn \times nD}{nO} = \frac{5 \times 33\sqrt{6}}{2 \times 19}, \text{ &c.}$$

$$AO = An + nO = \frac{5 \times 33\sqrt{6}}{2 \times 19} + \frac{22\sqrt{6}}{19} = \frac{11\sqrt{6}}{2}. \text{ Again}$$

$DF + FE : DE :: DF : Dp = 33 : 7$, whence $pE = 30 : 7$; & $Fp = DF \times FE - Dp \times pE = 440 : 49$, or $Fp = 20\sqrt{11} : 7$. Also $FE + Ep : Fp :: FE : FO = 2\sqrt{11} : 1$, and by the sim. \triangle 's, FOE, AOB ; $FO : FE :: AO : AB = 5\sqrt{66} : 2$. Again

$$FD + DE : FE :: FD : Fm = 11 : 2, \text{ whence } mE = 9 : 2.$$

Wherefore

Wherefore $Dm = FD \times DE - Fm \times mE = \frac{3}{4} \times \frac{90}{1} = \frac{27}{4} \times 33$

or $Dm = \frac{3}{2} \sqrt{33}$. Also

$DE + Em : Dm :: DE : DO = \sqrt{33}$; whence $Om = \frac{1}{2} \sqrt{33}$.

And $Cm \times mO = Fm \times mE$, or $Cm = \frac{Fm \times mE}{mO} = \frac{3}{2} \sqrt{33}$.

Therefore $Cm = Dm$ and $DC = 3\sqrt{33}$. Whence the area is

$\frac{AB \times DC}{2} = \frac{5}{2} \sqrt{33} \times \frac{3}{2} \sqrt{66} = \frac{15}{4} \times 33\sqrt{2} = \frac{15}{4} \times 33 \times$

$1.41421356 = 175.008928$ square chains $= 17.5$ acres,
nearly.

And thus the question was answered by Mr. Cunliffe;

Who observes "What is deduced previous to the calculation suggests an easy way of constructing the problem geometrically, and which may be as follows, *viz.*—With the given distances of the points, where the perpendiculars from the angles meet the opposite sides, let the triangle FDE be formed, and having bisected the angles FDE, FED, and DFE with the lines Dm, Em, and Fm, draw the lines AB, BC, and AC respectively perpendicular to the former, through the points D, E, and F, and they will form the triangle required".

Solutions were also received from Messrs. Francis, Lowry, and Swale.

IV. QUESTION 244, answered by Mr. Cunliffe.

Plate 29, Fig. 570. Let the triangle FAE represent a vertical section of the wall at right angles to the face next to the water, and let the point S in AE denote the surface of the water. Draw FP to any point Pm in the line AS. By the principles of Hydrostatics, the pressure of the water at P against AE will be expressed by $m \times SP$, where m denotes the specific gravity of the water; and by the resolution of Forces, its force in a direction perpendicular to FP will be expressed by $m \times SP \times (PA \div FP)$: and therefore the effect of the pressure of the water against the point P to turn the triangle FAE about F will be expressed by $m \times SP \times (PA \div FP) \times FP = m \times SP \times PA$.

Consequently the effect of the pressure of the water against the whole line AS, to turn the triangle FAE about F will be expressed by the sum of all the $m \times SP \times PA$.

Now to find the sum of all the $m \times SP \times PA$, put $AS = d$
 $SP = x$, then $PA = d - x$; and the sum of all the
 $m \times SP \times PA = \text{flu. } m \times x(d - x)$ when $x = d$:
but $\text{flu. } mxx(d - x) = \text{flu. } mdxx - \text{flu. } mxx$

$$= m \times \left(\frac{dx^2}{2} - \frac{x^3}{3} \right),$$

and when $x = d$, the fluent becomes

$m \times \left(\frac{d^3}{2} - \frac{d^3}{3} \right) = \frac{md^3}{6} = \frac{m}{6} \times AS^3$, which as is shewn above
expresses the effect of the pressure of the water upon the line AS
to turn the triangle FAE about F.

To find the effect of the weight of the triangle FAE to turn it
in a contrary direction. From G, the centre of gravity of the
triangle, draw GN perpendicular to FA, and let W denote the
effect of the weight of the triangle FAE to turn it about F in a
direction contrary to that of the action of the water will be ex-
pressed by

$$\begin{aligned} W \times FN &= \frac{1}{2} \times FA \times AE \times n \times FN \\ &= \frac{1}{2}n \times FA \times AE \times FN \\ &= \frac{1}{2}n \times FA^2 \times AE; \end{aligned}$$

because $W = \frac{1}{2}n \times FA \times AE$ and $FN = \frac{1}{2} \times FA$; where n
denotes the specific gravity of the wall.

Therefore when the wall just supports the fluid, the two pre-
ceding forces must be equal to each other, viz.

$$\frac{1}{2}n \times FA^2 \times AE = \frac{1}{6}m \times AS^3 \text{ whence}$$

$$FA^2 = AS^2 \times \frac{m \times AS}{2n \times AE}, \text{ or } FA = AS \sqrt{\frac{m \times AS}{2n \times AE}}.$$

In the present case where $AS = 10$, $AE = 12$, $m = 7$, and $n = 11$,

$$FA = AS \sqrt{\frac{m \times AS}{2n \times AE}} = 10 \sqrt{\frac{35}{132}} = 5.149286 = 5 \frac{3}{20}$$

feet nearly, the thickness of the wall at the bottom, just sufficient
to support the fluid.

Mr. Buffham and Marrat also sent answers to this question.

V. QUESTION 245, answered by Mr. Gregory, the Proposer.

Plate 29, Fig. 571. It has been demonstrated that the altitude AK of the greatest inscribed triangle is equal to $\frac{1}{2}$ of the transverse diameter; it has also been demonstrated that the altitude LB of the least circumscribing triangle is $\frac{1}{2}$ of the transverse: And it

it will readily appear, since LF is half of LB , that $EF = HK$ is $= \frac{1}{4}BM$. Therefore, the triangles LMN and AHI are similar, and as the altitude of the former is double that of the latter, its area is quadruple; and the difference between the areas is equal to thrice AHI . Hence 70.148025 the given difference divided by 3 gives 23.382675 area of AHI . Let this be divided by 9 $= AK = \frac{1}{4}AB$, the quotient is $2.598075 = \frac{1}{2}\sqrt{3} = HK$.

Then, by the nature of the ellipse,
 $AK \times KB : HK^2 :: AG \times GB : GC^2$;

that is as $27 : \frac{27}{4} :: 36 : \frac{36 \times 27}{27 \times 4} = 9 = GC^2$.

Consequently $GC = 3$ and $CD = 6$ the conjugate required.

The same, answered by Miss Susan May.

Plate 29, Fig. 572. Let $BEAF$ represent the ellipse required, QPR the least circumscribing triangle, and EBF the greatest inscribed one.

Now it is manifest from the first solution to quest. 170 of Repository, that

$GP = GB = \frac{1}{4}BA = 9$, and

$\Delta QPR = 27 \times GE (BR \times BP) = 4 \Delta EFB (GE \times GB)$; therefore $3GE \times GB = 70.148025$, or $GE = 70.148025 \div 27 = 2.598075$.

And by the property of the ellipse,

$(\text{conjugate})^2 : 12^2 :: GE^2 : BG \times GA = \frac{3}{16} (12)^2$, that is,

the conjugate $= 4GE \div \sqrt{3} = 10.3923 \div 1.73205 = 6$.

The same, answered by Mr. William Marrat, Boston.

Plate 29. Fig. 572. Let AFB be half the elliptical table, and draw the lines as per figure. The greatest inscribed ΔBFG is when the altitude BG is $\frac{1}{2}$ of the transverse axis AB ; and the least circumscribing Δ (by Prob. 5, Emerson on Curve Lines) is, when the subtangent $PG = GB$; and by Prop. IX, Ellipse, Hutton's Conics,

$$PB : PO :: PG : PA$$

and alternately $PB : PG :: PO : PA$;

but $PB = \frac{1}{2}PG$, therefore $PO = \frac{1}{2}PA$, and conseq. $AG = GO$.

Now $GB = \frac{1}{4}AB = 9$, and $PB = 18$, therefore putting $GF = x$, twice the area of the $\Delta BEG = 9x$, and twice that of the $\Delta PBR = 96x$; therefore by the question $96x - 9x = 70.148025$; hence $x = 2.598075$.

Then,

Then, by the property of the ellipse,
 $AG \times GB : GF^2 :: AB^2 : CD^2 = 36$.
Consequently $CD = 6$, the conjugate diameter required.

The same, answered by Mr. G. Buffham.

Plate 29, Fig. 572. Let the ellipse AEBF represent the table, O its centre, and let lines be drawn as in the figure. Put t and c for the transverse and conjugate diameters respectively; put also $BG = x$. Then, by conics, $GE = (c \div t) \sqrt{(tx - x^2)}$, and the area of the $\triangle BEF = (c \div t) x \sqrt{(tx - x^2)}$, which by the question must be a maximum, or $tx^3 - x^4$ a maximum, which being fluxed and reduced gives $x = \frac{3}{4}t = 9$; and, by substitution, $(c \div t) x \sqrt{(tx - x^2)}$, becomes $\frac{3}{16}tc \sqrt{3}$.—By the

Scholium to Prob. 8. Simpson on the maxima et minima of geometrical quantities, tangents drawn to the ellipse through the points E and F form the least circumscribing \triangle ; for, by the said scholium, it is a minimum when the subtangent $GP = BG$; and per conics,

$OG : GA :: BG : GP$; therefore $OG = GA$, or
 $BG (x) = \frac{1}{2}AB (\frac{3}{4}t)$ as before

Whence the area of the triangle PQR is easily found to be $(4c \div t) x \sqrt{(tx - x^2)} = 3c \sqrt{27}$, by substituting for x and t . Then per question $3c \sqrt{27} - (3 \div 16) tc \sqrt{3} = 70^{\circ}148025$. Hence $c = 6$ the conjugate required.

The same again, by Mr. John Whitley.

Plate 29, Fig. 572. CONSTRUCTION. Let ABCD represent the elliptic table, AB the given transverse, and CD the required conjugate diameter, and SLMN a rectangle equal in area to the third part of the given difference of the triangles. Upon AB, as a diameter, describe the circle ALBH, and bisect its radius AO in G, and draw IGH \perp to AB, meeting the circle in I and H; in HG take the point F so that $BG : MN :: ML : GF$, make OC ($= OD$) perpendicular to AB and such that $IG : FG :: AO : OD$, so shall CD be the required conjugate.

DEMONSTRATION. Join IB, HB, and in BG, FG, produced take PG and GE respectively equal to BG and FG. Join also PF, PE, which produce to meet RBQ drawn parallel to FE in Q and R, also join BF, BE. Then by construction $AG = GO$, therefore the $\triangle BHI$ is equilateral, and is, therefore, the greatest that can be inscribed in the circle; and because $PG = GB$, PE

PE = EQ = BE, therefore the Δ s PFE, BFE, BEQ, and BFR are equal in all respects. But by the scholium to Theorem 8, Simpson's Geometry, on the max et min. of quantities, the Δ BFE is half of the greatest parallelogram that can be inscribed in the triangle PQR; it also follows from the said scholium that the triangle PBR is the least that can be circumscribed about the curve ACB, therefore the Δ BFE which is double of the Δ BFG is a maximum, also the Δ PQR which is double the Δ PBR is a minimum. And by a property of the ellipse, $AG \times GB = IG^2 : FG^2 :: AB^2 : CD^2$, wherefore $IG : FG :: AB : CD$; but by construction $BG : NM :: ML : GF$, therefore, Euc. 16, VI, $BG \times FG = SL \times LM =$ the area of the triangle FBE (per *constr.*) $= \frac{1}{2} PQR = \frac{1}{2} PQR - \frac{1}{2} BFE$. *Q.E.D.*

The same otherwise, by Mr. Cunliffe, of Bolton.

It is well known that an equilateral Δ is the greatest that can be inscribed within, and the least that can be circumscribed about any given circle. Therefore if a circle with its greatest inscribed, and least circumscribing Δ s, be imagined to be projected *orthographically* upon a plane which makes an \angle with the plane of the figure, the projection will be an ellipsis with its greatest inscribed and least circumscribing Δ s. And the difference between the greatest inscribed and least circumscribing Δ s in the circle will be to the difference between the greatest inscribed and least circumscribing Δ s in the ellipsis, as the transverse to the conjugate diameter of the ellipsis. This is well known to those acquainted with the principles of the orthographic projection.

This being premised, let d denote the transverse, and c the conjugate diameters of the ellipsis; then it is well known that $\frac{1}{2}d\sqrt{3}$ will express the side of an equilateral Δ inscribed in the circle whose diameter is d ; $(9 \div 16)d^2\sqrt{3}$ its area. Also $d\sqrt{3}$ will express the side of the least circumscribing equilateral Δ , which is manifestly double the side of the inscribed Δ ; therefore its area will be four times the area of the inscribed Δ , and consequently the difference between the areas of the said Δ s will be equal to thrice the area of the inscribed Δ or $(9 \div 16)d^2\sqrt{3}$. Now let A denote the difference of the areas of the greatest inscribed and least circumscribing Δ s in the ellipsis; then $d : c :: (9 \div 16)d^2\sqrt{3} : A$; whence $(9 \div 16)d^2\sqrt{3} = dA$, or $c = 16A \div 9d\sqrt{3} = (16A \div 27d) \times \sqrt{3} = 6$ feet.

VI. QUESTION 246, *answered by Mr. Bosworth, the Proposer.*

In Fig. 573, Pl. 29. Let AB and AC represent the two mirrors, and a the small object on AB, placed 6 inches from B. It has

has been proved that the distance bc of the image formed by reflection from AC , is equal to the distance of the object a from that mirror; and that the images l, g, c, e, i , formed by continual reflections from both mirrors are in the circumference of a circle whose centre is A and whose radius is the distance of the object a from that centre. See *Enfield's Institutes of Nat. Phil.* Prop. CI, and CII; and *Wood's Optics*, Prop. XIII. XIV. From the known principles of optics we are certain that ac, eg , and il , are perpendiculars to AC , and bisected by it; in like manner ce, gi , and lm , are perpendiculars to AB , by which they are bisected. It follows, then that the \angle s ace, ceg, egi, gil, ilm , are each = the given $\angle CAB = 15^\circ$; and, by Euc. III. 20. the arcs lg, gc, ca, ae, ei, im , each = 30° —whence the number of images formed on the two mirrors = $180 \div 30 = 6$; but the last is not perfect, as the centre of it falls on A , the point of intersection, and therefore only half of it is caught by the mirror. If twice the \angle of inclination be not a measure of 180° ,—the number of images formed will be that whole number which is next inferior to the quotient of 180° by twice the angle.

To find the distance of each image behind the surface of the mirror upon which it is formed, we must consider that the first distance is denoted by the sine of the same number of degrees as the inclination of the mirrors; the second is the sine of twice that number; the third of three times, and so on—for bc is, evidently, the sine of 15° , in the present case; de of 90° —and so of the rest. These distances may easily be calculated by a table of natural sines; thus,

As 1 (Rad): $2588190 = \text{fin. of } 15^\circ \therefore 86(\text{Rad}): 93172840 = bc$
 $5000000 = \dots \dots 30^\circ \therefore 36 \dots : 18^\circ \dots = de$
 $7071068 = \dots \dots 45^\circ \therefore 86 \dots : 254556648 = fg$
 $8660254 = \dots \dots 60^\circ \therefore 36 \dots : 311769144 = hi$
 $9659258 = \dots \dots 75^\circ \therefore 36 \dots : 347733288 = kl$
 $36 \dots \dots = lm$

The same, answered by Miss Susan May.

Plate 29, Fig 574, 575. Let CA' , CB' , be two plain mirrors inclined in a given angle $A'CB'$, and let a be an object placed between them. With the distance Ca and centre C describe a circle. Draw $aO \perp$ to CB' meeting the circle at O , and $aI \perp$ to CA' meeting the circle at I . Draw also $OK \parallel aI$, $ID \parallel aO$, $DL \parallel OK$, $KE \parallel DI$, $EM \parallel DL$, $FL \parallel KE$, and so on. Then because of the parallels it is evident that DI , EK , LF , GM , HN , &c. are \perp to CB' , and that OK , DL , EM , FN , GQ , &c. are \perp to CA' ; therefore by the property of the circle,

em

$am = mo$, $In = nD$, $Ko = oE$, $Lp = pF$, $Mq = qG$, $Nr = rH$, &c. and $ax = xI$, $Ow = wK$, $Dv = vL$, $Ez = zM$, $Ft = tN$, $Gs = sO$, &c.

Now it is well known that in a plain mirror the object appears to be as far behind as it is distant from the mirror, therefore O will be the place of the object a, as reflected from the mirror B'C, this image will be reflected again from O to K by the mirror A'C, then from K to E by the reflection of BC, and so on.

Again, I will be the place of the image of the object as reflected by A'C, this image will be reflected by B'C from I to D, by AC from D to L, and so on.

Therefore O, D, E, F, G, H, &c. will be the number of images of the object reflected by the mirror B'C, and I, K, L, M, N, O, &c. those reflected by the mirror A'C. Now when the object is placed on one of the mirrors, as A'C, the images at I, D, L, F, N, &c. will be wanting, and the others will appear as in Fig. 575, where it is evident that the arcs aO , aK , OE , KM , Ez , NQ , are equal, each being equal to twice the given $\angle aCb = 30^\circ$; hence $180 \div 30 = 6$, the number of images formed on the two mirrors, the last of which is imperfect, as it falls on the point of intersection of the mirrors. The distances Om , wK , oE , zM , and Gq , are easily determined, for they are respectively the sines of 15° , 30° , 45° , 60° , and 75° . Hence by Page 26, of Emerson's Trigonometry— $Om = 18\sqrt{2 - \sqrt{3}}$, $wK = 18$, $oE = 18\sqrt{2}$, $zM = 18\sqrt{3}$, and $Gq = 18\sqrt{2 + \sqrt{3}}$.

Messrs. Cunliffe, Gregory, and Lowry, also favoured us with neat solutions to this question.

VII. QUESTION 247, answered by Mr. William Francis, Teacher of the Mathematics at Maidenhead.

Plate 29, Fig. 576. Let ABCDE be the pentangular garden, and o the centre of its circumscribing circle. Let lines be drawn as in the figure, and draw the radius Ao which will be \perp to EB at h. Now it is evident that the figure cdeab will be a pentagon, and therefore the most regular inscribed curve will be a circle whose radius is oh. The $\angle hAE = 54^\circ$ and $AE = 50$; hence Ah is found $= 29.390$, and $hE = 40.45085$: but 10 times hE is $=$ to the sum of all the walks $= 404.5085$. Again, Ao is found $= 42.5332$, and $Ao - Ah = oh = 13.1432$ the radius of the circle, and its area $= 542.697$ yards, which at 6d. per yard amounts to 1 gl. 11s. 4d.

The same, answered by Mr. Gregory, the Proposer.

It is plain that the angles BAC, and BCA are each $= 360 \div 10 = 36^\circ$, and hence ABC $= 180 - 72 = 108^\circ$. Therefore,

as S. of 36° : S. of 108° :: AB (50) : 80.9016852 = AC = AD = BD = BE = EC; the sum of the lengths of these five walks is consequently = to $80.9016852 \times 5 = 404.588426$ yards. Now $CaB = CAB + ABE = 36^\circ \times 2 = 72^\circ$, and $CBD = 180^\circ - (CdB + ACB) = 72^\circ$: therefore CdB is an isosceles triangle, and $Cd = CB$: in the same way it is shewn that $Ab = AB$ or CB .

Hence $Ce = AC - BC = 30.9016852$, and $de = AC - 2Ce = 19.0983148$. After a similar way we might find ae , ba , cb , or $dc = 19.0983148$. It is manifest that $AdB = 108^\circ - 36^\circ \times 2 = 108^\circ$; and of course the opposite angle $cde = 108^\circ$: thus it may be shewn that the angles dea , eab , abc , and bcd , are each $= 108^\circ$ —and, consequently the figure $abcde$ having five equal sides, and five equal angles, is a regular pentagon: and the most regular inscribed curve will be a circle. Then, as S. of AoB : S. of ABo :: AB : $Ao = 42.5332$; also as, Rad. : AB :: S. of EBA : $Ah = 29.390$; hence $Ao - Ah = 13.1432$ the radius of the circle. The content of which is 542.697 square yards; and this at 6d. per yard amounts to 13l. 11s. 4d. the expence of digging the pond.

The same, answered by Tyro Philomatheticus.

Let ABCDE represent the garden, &c. Then it is evident that the pond must be a circle, the centre of which is the centre of the pentagon; it is likewise manifest that Dko is a right angle, and that $Dk = kB$, and from the nature of the figure $oDk = 18^\circ$ and $kCD = 54^\circ$; therefore as, Rad. : DC (50) :: S. of kCD (54°) : $Dk = 40.45085$, and $40.45085 \times 10 = 404.5085$, the sum of the lengths of all the walks; and as, S. of Dok (72°) : Dk (40.45085) :: S. of oDk (18°) : $ok = 13.1432$ the radius of the pond; consequently its area is 542.697 square yards, which at 6d. per yard amounts to 13l. 11s. 4d. the expence of digging.

The same, answered by Mr. John Whitley.

Let ABCDEA represent the pentangular garden, AD, BE, AC, DB, and CE, the walks intersecting each other in the points b, c, d, e, a ; then, by *Emerson's Geometry* IV. 43, $DEdC$, $DEAc$, $EABa$, $ABCb$, and $BCDc$, are parallelograms, and therefore the angles CdE , CDE , DeA , DEA , &c. are equal, and consequently $abcdea$ is a pentagon, and the curve which touches all its sides will be a circle, the centre of which will be, the centre of that circle which circumscribes the given pentagon. Let o be the centre and draw $og \perp$ to AD , and through o draw AoH meeting DC in H . Then, by Cor. 3. of the above quoted proposition, we have as,

$1 : (1 + \sqrt{5}) \div 2 ::$ so is the side of the pentagon : to the diagonal, or the length of one of the walks ; that is,

As $1 : (1 + \sqrt{5}) \div 2 :: DC (= 50) : DA = 25(1 + \sqrt{5})$;
also, by Prop. 44, of the same Book,

$As 5 - \sqrt{5} : 2 :: DC : oA = 2 \times 2500 \div (5 - \sqrt{5}) = 1250 + 250\sqrt{5}$;
and, by sim. Δ s, $DA : DH :: oA : og$, that is,

$25(1 + \sqrt{5}) : 25 :: \sqrt{(1250 + 250\sqrt{5})} : \sqrt{(1250 + 250\sqrt{5})} \div (1 + \sqrt{5}) = og$ the radius of the circle touching the walks, the area of which is easily found $= 542.7$ square yards nearly, which at 6d per yard comes to 13l. 11s. 4d. and the sum of the lengths of all the walks is equal to $(1 + \sqrt{5}) \times 25 \times 5 = 404.5085$ yards.

W. W. R.

Ingenious solutions were also received from Messrs. Buffham, Lowry, May, and Thornoby.

VIII. QUESTION 248, answered by Mr. John Lowry.

The curve required is an exponential one, whose equation is $x = y^y$, where x represents the abscissa, and y the corresponding ordinate.

For if Y be put for the hyperbolic logarithm of y , then $x = y \times Y$ and $\dot{x} = \dot{y} \times Y + \dot{Y} \times y$; but by the nature of logarithms $\dot{Y} = \dot{y} \div y$; then by substitution $\dot{x} = \dot{y} \times Y + \dot{y}$, therefore $\dot{y} \dot{x} \div \dot{y}$ (the general expression for the subtangent) $= y \times Y + y$: but $x = y \times Y$; therefore the subtangent $= x + y$, and the distance of the subtangent from the vertex is $=$ to the ordinate y .

The same, answered by Mr. Marrat, of Boston.

If x denote the abscissa and y the ordinate of the curve required ; then by the property of tangents, $\dot{y} : \dot{x} :: y : \text{the subtangent}$, that is, by the nature of the question, $\dot{y} : \dot{x} :: y : y + x$, and by reduction $\dot{y} \dot{x} - \dot{y} y - \dot{y} y = 0$. To find the fluent put $y = zx$, then $\dot{y} = zx + zx$, therefore by substitution we obtain $z^2 x \dot{x} = -x^2 z - x^2 z \dot{x}$; therefore $\frac{\dot{x}}{x} = -\frac{z}{z^2} - \frac{\dot{z}}{z}$, the fluent of which is,

hyp. log. $x = \frac{1}{z} - \text{hyp. log. } z$: but $z = y \div x$; therefore

hyp. log. $x = \frac{x}{y} - \text{hyp. log. } \frac{y}{x}$; hence $y \times \text{hyp. log. } y = x$ and consequently $y^y = x$, the equation of the curve required.

VOL. III.

M

The

The same, answered by Tyro-Philomatheticus.

By the question, $\frac{yx}{y} = x + y$, (x being the abscissa, y the ordinate, and $\frac{yx}{y}$ the general expression for the subtangent); therefore to find the relation of x and y , suppose $zy = x$, then by substitution we get $y(zy + yz) = zyy + yy$, or $yz = y$, and $z = \frac{y}{y}$; hence $z = h. l. y$, and the equation of the curve is $x = y \times h. l. y$.

The same, answered by Mr. John Whitley.

Let $x =$ the abscissa, and $y =$ the ordinate of the required curve; then by the question $y = \frac{yx}{y} - x$; consequently $\frac{yx - xy}{y} = \frac{y}{y}$; the fluent of which gives $\frac{x}{y} = \text{hyp. log. } y$; whence $x = y \times \text{hyp. log. } y$ the equation of the curve required.

This question was likewise ingeniously answered by Messrs. Cunliffe, Gregory, and Thornoby.

IX. QUESTION 249, answered by Mr. Johnson, of Birmingham.

For the sum of the squares.

Construction. Pl. 30, Fig. 579. Join the three given points A, B, C; from C draw the diameter CSV, and let it be divided in the given ratio at O. On OC as a diameter describe a semi-circle, and from R, the middle of AB, apply RP to cut or touch the semi-circle, as at P, and such that $2AP^2 + 2RP^2 =$ the given sum of the squares; then through P and C draw the chord CPD; join AP, BP, and it is done.

Demonstration. By Constr. CO : OV is = to the given ratio; and by Euc. 19, VI. Stone's Edition, CO : OV :: CP : PD; therefore CD is divided, at P, in the given ratio; and $2AR^2 + 2RP^2 =$ by constr. to the given sum of the squares $= AP^2 + BP^2$.

For the difference of the squares.

Having as above joined the points A, B, C, drawn the diameter from C, and divided it in the given ratio at O, and on OC as a diameter described a semi-circle; then from R, the middle of AB, take RI such that $AB \times 2RI =$ the given difference of the squares, and at I erect the perpendicular IP to cut or touch the semi-circle at P, through which, and C, draw the chord CPD. Join AP, BP, and it is done.

The same, answered by Mr. John Lowry.

ANALYSIS. Pl. 30, Fig. 580. Suppose the chord CD to be really drawn as required. Join the points A and B, and draw the diameter CS, which divide at I in the given ratio. On CI as a diameter let a circle be described, and join IP, DS. Then, because of the right angles at P and D, the Δ s ICP, SCD are similar; therefore the chord CD will always be divided in the given ratio by the circle CIP. Now when the *sum* of the squares of AP, BP is given, bisect AB at H, and join HP; then $AP^2 + BP^2 = 2AH^2 + 2PH^2$; but AH is given; therefore PH is given, and H is a given point, therefore the locus of the point P is a circle whose centre is H and radius HP, and consequently the intersection of this circle with the circle ICP will determine the point P.

Since AH is constant, the sum of the squares of AP, BP, will be the greatest or least possible when HP is the greatest or least, that is when it passes through the centre of the circle ICP.

Again when the *difference* of the squares AP, BP is given.

Draw PK \perp to AB; then $AP^2 - BP^2 = AB \times 2KH$, therefore KH is given, and the locus of the point P is the straight line KP given by position; therefore its intersection with the circle ICP will determine the point P.

The difference of the squares will evidently be a maximum when KP touches the circle at P.

The same, answered by Mr. Swale.

Pl. 30, Fig. 581. Suppose the chord CD drawn as required, and divided in the given ratio at P. Join AB and bisect it at E, and join AP, BP, and EP. Then since $AP^2 + PB^2 = 2PE^2 + \frac{1}{2}AB^2$ is a given space, and AB a given line, it follows that PE is also given. Now join CE and draw DG parallel to PE meeting CE at G. By parallels $PE : DG = CP : CD$, a given ratio, or DG a given line: But, $CG : CE = CD : CP$, and therefore, because CE is given, the point G is a given one, that is, D is a given point.

Hence for the sum of the squares.

Join the given points A, B, and bisect AB at E, and take the line EP such, that $\frac{1}{2}AB^2 + 2PE^2$ = the given space; join CE and make EG to EC in the given ratio, and to the given circle, apply GD a 4th proportional to CE, CG, and EP; then join CD and it is done.

For the difference of the squares.

Demit upon AB the \perp PF, join CF, and let DH, drawn parallel to PF, meet CF at H. Then since $AP^2 - PB^2 = AF^2 - FB^2$ = a given space, the point F will be given, since AB is a given line. Also, because $FH : FC = PD : PC$, is a given ratio, the point H will be given. Whence in this case, join AB and divide it in F, so that $AF^2 - FB^2$ may be = to the given space; join CF, and take $FH : FC$ = the given ratio, and draw HI \perp to AB, meeting the circle in D: then joining C, D, it is done.

Meffrs. Cunliffe and Whitley sent neat solutions to this question.

X. QUESTION 250, answered by Mr. Cunliffe.

The area and the perimeter of the polygon being given the radius of the inscribed circle becomes known; for the area is equal to a rectangle under half the perimeter and the radius of the inscribed circle. Therefore let r denote the radius of the inscribed circle, z one of the sides of the polygon, n the number of its sides, and p the given perimeter thereof. Let also, c denote the length of that arc of the inscribed circle whose tangent is t , and put $c = 3^{\circ}14159 \&c.$

Then it is obvious that $2nt = p$, and $2nz = (p \div t)z = 2rc$, the circumference of the inscribed circle. Moreover it is well known that

$$z = t - \frac{t^3}{3r^2} + \frac{t^5}{5r^4} - \frac{t^7}{7r^6} + \&c.; \text{ wherefore,}$$

$$\begin{aligned} 2nz &= (p \div t)z = (p \div t) \times (t - \frac{t^3}{3r^2} + \frac{t^5}{5r^4} - \frac{t^7}{7r^6} + \&c.) \\ &= p \times (1 - \frac{t^2}{3r^2} + \frac{t^4}{5r^4} - \frac{t^6}{7r^6} + \&c.) \\ &= 2rc; \text{ or} \end{aligned}$$

$$1 - \frac{t^2}{3r^2} + \frac{t^4}{5r^4} - \frac{t^6}{7r^6} + \&c. = 2rc \div p; \text{ whence,}$$

$$1 - \frac{3t^2}{5r^2} + \frac{3t^4}{7r^4} - \frac{3t^6}{9r^6} + \&c. = 3r^2 - \frac{6r^2c}{p} = q, \text{ a given quantity,}$$

gity, because both r and p are given; and by reverting the series

$$t = q^{\frac{1}{2}} + \frac{3q^{\frac{3}{2}}}{10r^2} + \frac{141q^{\frac{5}{2}}}{1400r^4} + \frac{1411q^{\frac{7}{2}}}{42000r^6} + \text{ &c.}$$

$$= q^{\frac{1}{2}} \times \left(1 + \frac{3q}{10r^2} + \frac{141q^2}{1400r^4} + \frac{1411q^3}{42000r^6} + \text{ &c.} \right)$$

Now t being determined, n will be found from the equation $n = p \div 2t$.—In all cases when p , the perimeter of the polygon does not much exceed $2rc$, the circumference of the inscribed circle, the preceding series expressing the value of t will converge fast, because in those cases the value of q will be but small. To prove this, put $2rc + v = p$, then

$$q = 3r^2 - \frac{6r^3c}{p} = 3r^2 - \frac{6r^3c}{2rc + v} = \frac{3r^2v}{2rc + v}, \text{ which, because}$$

v is small, will evidently be small.

But the solution of any particular case of the question may likewise be easily made out from what is done above by the method of trial and error. For it has been found that $pz \div t = 2rc$, or $z \div t = 2rc \div p$, that is, the ratio of an arc of a circle to its tangent is given, from whence, by a few trials, the arc itself, as well as the tangent, may be found, and from thence n as before.

XI. QUESTION 251, *answered by Mr. Lowry.*

Plate 30, Fig. 582. Let CB be the given distance of the illuminated point from the point directly under the candle, and BA the required height of the candle. Join CA, and from B upon CA drop the \perp BD.

Now the effect of a particle of light to illuminate an object being directly as the sine of the angle of incidence, and reciprocally as the square of the distance, or directly as BD, and inversely as CA^2 we have $BD \div AC^2$ a maximum. But by sim. Δ s $CA^2 : CB^2 :: CB^2 : CD^2$; therefore $BD \div AC^2 = (CD^2 \times BD) \div CB^4$; but CB^4 is a constant quantity, therefore when $BD \div AC^2$ is a maximum, $CD^2 \times BD$ will be so too; and by Simpson on the max. et min. this will happen when $CD^2 = 2BD^2$, or when $CB^2 = 2BA^2$; therefore $BA : BC :: 1 : \sqrt{2}$, or as the side of a square to its diagonal.

The same, answered by Tyro Philomatheticus.

Let a = the given distance of the point to be illuminated from the point directly under the candle, and x = the required altitude.

Then it is well known that $\frac{1}{a^2 + x^2}$ will be as the number of particles, and the force of each being as the sine of the angle of incidence, we have $\frac{x}{\sqrt{a^2 + x^2}}$ as the force of one particle; therefore

$$\frac{x}{\sqrt{a^2 + x^2}} \times \frac{1}{a^2 + x^2} = \frac{x}{(a^2 + x^2)^{\frac{3}{2}}}, \text{ is as the force or power}$$

of the flame to illuminate the said point, which by the question, must be a *maximum*. Put into fluxions and reduced gives $x = a\sqrt{\frac{1}{3}}$.

XII. QUESTION 252, *answered by Tyro Philomatheticus.*

From a little consideration, it will manifestly appear that the length of the curve will be found by the expression given for the involute of a circle; that is, putting $p = 3.141592 \&c.$

$$\left\{ l - \left(\frac{a}{2p} + \frac{1}{4}b \right)^2 \right\} \div \left(\frac{a}{p} + b \right) = \text{the length of the curve.}$$

XIII. QUESTION 253, *answered by Mr. Lowry.*

By the scholium to Prop. XXXV, Emerson's Mechanics. "A body projected on an inclined plane will describe a parabola. And if the velocity of projection upon the plane to be the velocity of a projectile in the air; as the relative gravity on the plane to the absolute gravity; and both projected at the same obliquity, the same parabola will be described in both cases." Now the relative gravity on the plane is to the absolute gravity, as the sine of the angle of elevation to radius, that is, as sine of 10° : radius :: 8 feet (the velocity of projection on the plane) to 46.0701 feet, the velocity necessary to describe the same parabola in free space; and $(46.0701)^2 \div (4 \times 16 \frac{1}{2}) = 32.99151$ feet; the space which the ball must descend to acquire that velocity. Suppose the plane of the table to be placed in a vertical direction, A the point from whence the ball is projected, (Plate 30, Fig. 587) K the centre of the table, and F the place where the ball quits it. Draw KIS, QABD, \perp to the horizon, and take AQ = QQ' = 32.99151; draw the indefinite right lines QSC, Q'C'C, and through A draw the tangent AC', to touch the circle at A and meet Q'C' at C', and from C' to SK, apply Cu = CA; then draw Au, and it is the direction required, as is evident from Prop. IV. Page 37 and 38 of Burrow's

Elegant Little Essay on Projectiles; and by the rules there given the angle KAV is found $= 30^\circ 41' 35''$. Again with the distances KS , AQ , and centres K , A , describe two arcs intersecting in P : then P will, by the same essay, be the focus of the parabola, and CQO its directrix.

Join AG , AK , KP , and KF , and draw OPN parallel, and AIL , KBM , and $FEDN$ perpendicular to ADQ . Then by the property of the circle $GI = AG^2 \div 2GK = 416'$ and $IR = 239.583'$, $AI = 9.992$, and by trigonometry $\angle AKI = 4^\circ 46' 25''$. And in the $\triangle APK$ the three sides are given to find $\angle AKP = 8^\circ 59'$; therefore the $\angle PKM$ is found $= 81^\circ 14' 35''$, and KM and $PM = 78.488$ and 509.39 respectively. Hence $KP - PM = PO = 6.091 =$ half the latus rectum $= \frac{1}{2}p$.

Put $a = KM$ or HE , $b = KF$, and $x = FE$.

Then by the property of the parabola

$$p : 2KM + FE :: FE : EK, \text{ or}$$

$$p^2 : (2a + x)^2 :: x^2 : b^2 - x^2; \text{ therefore}$$

$$p^2b^2 - p^2x^2 = 4a^2x^2 + 2ax^2 + x^4, \text{ or}$$

$x^4 + 2ax^2 + (4a^2 + p^2)x^2 = p^2b^2$, and from the resolution of this equation x is found $= 9.027$, and $MN = 119.66$. And by Dr. Hutton's Mensuration the arc HF is found $= 735.083$, the arc $AH = 458.767$, and their difference $AF = 276.316$ the length of the track required.

XIV. QUESTION 254, *answered by Collator, the Proposer.*

Plate 30, Fig. 583. Let $ABCD$ be the ellipse, F and f its foci, AC and BD its major and minor axes. Take any point E between A and B , join Ef , FE . Now, since heat is inversely as the square of the distance, the heat coming from F will be as $\frac{1}{(FE)^2}$,

and the heat coming from f will be as $\frac{1}{(fE)^2}$; therefore the whole

heat will be as their sum, or as $\frac{1}{(FE)^2} + \frac{1}{(fE)^2}$; but whilst FE is greater than fE the square of FE decreases faster than that of fE increases, because the sum of FE , and fE is always the same, and therefore FE decreases just as fast as fE increases; consequently $\frac{1}{(FE)^2}$ increases faster than $\frac{1}{(fE)^2}$ decreases. Hence,

whilst

whilst E is between A and B the sum $\frac{1}{(FE)^2} + \frac{1}{(fE)^2}$ increases as the point E approaches to B, and decreases as the same point recedes from B; consequently the heat will be a maximum at B, and a minimum at A.

The same, answered by Mr. Lowry.

Let $\Delta EBCD$ be the given ellipse, F and f the foci, and F any point in the curve. Join fE , FE . Then, since the effect of heat is reciprocally as the square of the distance, the heat at F will be as $\frac{1}{(FE)^2}$, and that at f as $\frac{1}{(fE)^2}$, and therefore the whole effect will be as $\frac{1}{(FE)^2} + \frac{1}{(fE)^2}$; and since $CF + CG$ is given ($=$ the transverse diameter AC) it is evident $\frac{1}{(FE)^2} + \frac{1}{(fE)^2}$ will be a maximum when $FE = fE$, and a minimum when fE exceeds FE by the greatest distance possible, or when fE coincides with AC; therefore the greatest heat will be at the extremity of the conjugate diameter, and the least heat at the extremity of the transverse diameter.

Solutions to this question were also received from Messrs. Francis and Tyro Philomatheticus.

XV. QUESTION 255, answered by Mr. Cunliffe.

Plate 30, Fig. 584. Let ACD be drawn through the centres C and O, of both circles; join DG and produce it till $GM = GD$. Draw ME to touch the circle whose centre is C in E; through C and E draw the chord CEP, upon which demit the $\perp GV$, and EP will be bisected in V.

For, draw $MQ \parallel$ to EP , and meeting DP in Q, and produce VG to meet MQ in N. Then DP is at right angles to CP , therefore GN and DQ are parallel: but $GM = DG$ by the construction, therefore $MN = NQ$, or their equals, $EV = VP$.

Q. E. D.

If it had been required to draw the chord CP, such that demitting the $\perp GV$; EV and VP might have a given ratio, the construction would not have been materially different.

For

For in that case it had only been taking GM to DG in the given ratio, and the remaining part of the construction the same as before.

The same, answered by Mr. Johnson.

CONSTRUCTION. Plate 30, Fig. 585. On the line joining the points O, G, describe a semi-circle, and apply therein OK equal to half the radius of the circle whose centre is C; draw CP \parallel to OK and it is done.

DEMONSTRATION. Draw OI \perp to CP, and produce GK to meet CP at L; then we have to prove that EL = LP. Now by the property of the circle CI = IP, or CE + EI = IL + LP, and by construction \angle OK or \angle IL = CE; therefore \angle IL + EI = IL + LP, and taking IL from each, there remains EL = LP. *Q. E. D.*

If \angle OG be less than CE the problem is impossible.

The same, answered by Mr. Swale, the Proposer.

CONSTRUCTION. Plate 30, Fig. 586. Join CG, OG, and in OG take the point L such that $GL^2 - LO^2 =$ the difference between the square of CG and the sum of the squares of the radii CO, CA; draw LE \perp to GO meeting the former circle in E; and through C and E draw CP and it is done.

DEMONSTRATION. By the construction, $GL^2 - LO^2 = CG^2 - CO^2 - CA^2 = GE^2 - EO^2$, that is, $GE^2 + EC^2 - EO^2 = CG^2 - CO^2 = CG^2 - OI^2$.

But, because GF is perpendicular to CP, we have, $CG^2 = GE^2 + EC^2 + CE \times 2EF$; or $GE^2 + EC^2 - EO^2 = GE^2 + EC^2 + CE \times 2EF - OI^2$:

Then, $OI^2 - EO^2 = CE \times 2EF$.

Now, since HO = OI, it follows that,

$OI^2 - OE^2 = EI \times EH$; Hence

$CE \times 2EF = EI \times EH = CE \times EP$, by the circle;

Then $2EF = EP$, or $EF = FP$;

that is EP is bisected at F by the \perp GF. *Q. E. D.*

Ingenious solutions were also given by Messrs. Lowry and Whitley.

XVI. QUESTION 256, answered by Mr. John Whitley.

Plate 30, Fig. 588. Let lines be drawn as directed by the question, and join OB, OC, GC. By known properties

AC

Draw AF parallel to DB , and CG parallel to EB , each terminating in BB' ; also upon ED let fall the perpendicular BH .

By the question, $AB = A'F = a$; $BC = CG = c$; $AA' = BF = p$; $CC' = BG = r$; whence $B'F = q - p$ and $B'G = q - r$; and because of the parallels $A'F$, DB .

$B'F : A'F :: B'B : D'B = (A'F \cdot B'B) : B'F = aq : (q - p)$.

Also because of the parallels CG , EB ,

$B'G : CG :: B'B : EB = (CG \cdot B'B) : B'G = cq : (q - r)$.

Now in the $\triangle ABC$ all the sides are given; whence the $\angle ABC$ may be found by trigonometry. Moreover in the $\triangle DBE$, the sides DB and EB , together with their included $\angle DBE$, are given; to find the $\angle EDB$ or its supplement, the $\angle HDB$; and from thence the complement of this, or the $\angle DBH$ becomes known.

Suppose BM to be a meridian passing through B : the $\angle ABM$ is given by the question; therefore, as the $\angle DBH$ is given, the $\angle HBM$ becomes known, or the angle becomes known which the direction of the dip of the stratum makes with the meridian. Now HB may be easily determined from what has already been shewn: and at the length HB the stratum manifestly dips the depth BB' .

XX. QUESTION 260, *answered by Collator, the Proposer.*

Let A be the weight of the system, a the radius of the cylinder, x the distance of the centre of gyration from the centre of gravity, $m = 16\frac{1}{2}$, V the velocity generated in the time T , and S the space passed over by the weight P .

Now, by the property of the centre of gyration, if all the matter in the system were collected, and uniformly disposed over the circumference of a circle whose radius is x , and whose plane is perpendicular to the axis of motion, and passing through the centre of gravity of the system; the same force would generate the same angular velocity in the same time: also if instead of the matter being disposed at the distance of the centre of gyration, an equivalent mass be substituted at the surface of the cylinder, the same angular velocity will still be preserved; which mass will be

expressed by $\frac{x^2 A}{a^2}$.

By Atwood on *Rectilinear Motion and Rotation*, p. 36, $\frac{Q}{4} =$

$\frac{M}{m} \times \frac{v}{V}$; and, in this case, $M = m = P$; therefore $\frac{Q}{4} = \frac{v}{V}$

and

and $Q = N = \frac{Ax^2}{a^2}$; and the whole quantity of matter, moreover,

$$= \frac{Ax^2}{a^2} + P = \frac{Ax^2 + Pa^2}{a^2} = Q; \text{ but } \frac{Q}{q} = \frac{v}{V} = \frac{2m}{V}, \text{ and}$$

$$q = P, \text{ therefore } \frac{Q}{q} = \frac{Q}{P} = \frac{Ax^2 + Pa^2}{Pa^2} = \frac{2m}{V}.$$

$$\text{Hence } V = \frac{2m Pa^2}{Ax^2 + Pa^2} = 2\sqrt{(mS)}. \text{ Therefore}$$

$$2\sqrt{(mS)} \times Ax^2 + 2\sqrt{(mS)} \times Pa^2 = 2m Pa^2, \text{ or}$$

$$2\sqrt{(mS)} \times Ax^2 = 2m Pa^2 - 2\sqrt{(mS)} \times Pa^2, \text{ and}$$

$$x^2 = \frac{2m Pa^2 - 2\sqrt{(mS)} \times Pa^2}{2\sqrt{(mS)} \times A} = \frac{2Pa^2 \times \{m - \sqrt{(mS)}\}}{2\sqrt{(mS)} \times A}.$$

$$\text{Consequently } x = \pm \sqrt{\frac{2Pa^2 \times \{m - \sqrt{(mS)}\}}{2\sqrt{(mS)} \times A}}, \text{ the dis-}$$

tance of gyration from the centre of gravity; the latter of which being determinable by well known methods, it is unnecessary to pursue the investigation further.

XXI. QUESTION 261, answered by Mr. Cunliffe, the Proposer.

Fig. 591, Pl. 30. Let DBA represent the catenarian curve AD its axis, and DB its greatest ordinate, about which it revolves in the generation of the solid.

Draw any ordinate QP, and also the line PR parallel to AD meeting DB in R. Put l = the length of the curve APB, $AD = b$, $AQ = x$, $QP = y$, a = the tension of the curve at A, and $p = 3.1415926$, Then by the property of the curve

$$y = \frac{ax}{\sqrt{(2ax + x^2)}}; \text{ and by the writers on fluxions}$$

$$(RP)^2 \times p \times \text{flux.}DR = \frac{p \times (b - x)^2 \times ax}{\sqrt{(2ax + x^2)}}$$

$$= ap \times \left(\frac{b^2 x}{\sqrt{(2ax + x^2)}} - \frac{2b x x}{\sqrt{(2ax + x^2)}} + \frac{a^2 x}{\sqrt{(2ax + x^2)}} \right)$$

will express the fluxion of the solid generated by the evolution of the space DAPR about the ordinate DB: the fluent of which is

$$ap \times \left(\frac{x}{2} \sqrt{2ax + x^2} - \left(\frac{9a}{2} + 2b \right) \sqrt{2ax + x^2} \right) \\ + ap \times \left(b^2 + \frac{3a^2}{2} + 2ab \right) \times \text{h.l.} \left(\frac{a + x + \sqrt{2ax + x^2}}{a} \right);$$

and this expression is correct, for the whole will vanish or become $= 0$, when $x = 0$, as it ought.

But when $x = b$, the expression becomes

$$ap \times \left(b^2 + \frac{3a^2}{2} + 2ab \right) \times \text{hyp. log.} \left(\frac{a + b + \sqrt{2ab + b^2}}{a} \right)$$

$$- ap \times \left(\frac{3a + 3b}{2} \right) \sqrt{2ab + b^2} \text{ for the whole content of the}$$

the solid generated by the revolution of the space DPBA about the ordinate DB.

Again, by the property of the curve $a = (l^2 - b^2) \div 2b$; let this be written instead of a in the preceding expression for the solidity and it becomes

$$p \times \left(\frac{l^2 - b^2}{2b} \right) \times \left(\frac{3(l^2 - b^2)^2}{8b^3} + l^2 \right) \times \text{h.l.} \left(\frac{l+b}{l-b} \right) - \frac{3l^2}{8} \times \left(\frac{l^4 - b^4}{b^3} \right)$$

which is to be a *maximum* by the question, or

$$\left\{ \frac{3}{2} \left(\frac{l^2 - b^2}{2b} \right)^2 + l^2 \left(\frac{l^2 - b^2}{2b} \right) \right\} \times \text{h.l.} \left(\frac{l+b}{l-b} \right) - \frac{3l^2}{2} \left(\frac{l^4 - b^4}{4b^3} \right)$$

must be a maximum: therefore considering b variable and putting the fluxion of the expression $= 0$, there will be had

$$- \dot{b} \left(\frac{l^2 + b^2}{2b^2} \right) \times \left\{ \frac{3}{2} \times \left(\frac{l^2 - b^2}{2b} \right)^2 + l^2 \right\} \times \text{h.l.} \left(\frac{l+b}{l-b} \right) \\ + \dot{b} \times \left(\frac{3(l^2 - b^2)^2}{8b^3} + \frac{l^2}{b} \right) + 3l\dot{b} \times \left(\frac{l^4 + b^4}{4b^3} \right) \quad \left. \right\} = 0;$$

and dividing by $\frac{\dot{b}}{b}$

$$- \left(\frac{l^2 + b^2}{2} \right) \times \left\{ \frac{3}{2} \times \left(\frac{l^2 - b^2}{2b} \right)^2 + l^2 \right\} \times \text{h.l.} \left(\frac{l+b}{l-b} \right) \\ + l \times \left\{ \frac{3(l^2 - b^2)^2}{8b} + l^2 b \right\} + 3l \left(\frac{l^4 + b^4}{4b} \right) \quad \left. \right\} = 0; \text{ or}$$

$$- \left(\frac{l^2 + b^2}{2} \right) \times \left(\frac{9l^4 - 10l^2b^2 + 9b^4}{8b^3} \times \text{h.l.} \left(\frac{l+b}{l-b} \right) \right) \\ + l b \times \left(\frac{9l^4 + 2l^2b^2 + 9b^4}{8b^3} \right) \quad \left. \right\} = 0.$$

From

$$\text{From whence h. l. } \left(\frac{l+b}{l-b}\right) = \frac{2lb \times (gl + 2l^2b^2 + 9b^4)}{(l^2 + b^2) \times (9l^4 - 10l^2b^2 + 9b^4)},$$

which expression is well adapted for finding the value of b by the method of trial and error; and by a few approximations of this sort we get $b = l \times 7864616$, which is correct to the last decimal place.

Again, from the property of the curve,

$$DB = \left(\frac{l-b}{2b}\right) \times \text{h. l. } \left(\frac{l+b}{l-b}\right) = l \times 515172333, \text{ or}$$

$$CB = l \times 1.030344666.$$

W. W. R.

☞ All the properties of the catenary mentioned in the solution to this and question 265 may be seen, together with their investigations, in Dr. Hutton's Mathematical Dictionary.

XXIII. QUESTION 263, *answered by Collator, the Proposer.*

Plate 31, Fig. 603. Let ADB be a great circle of the earth or the equator; C its centre; AF the spiral. Put $r = AC =$ rad.; $m = 16 \frac{1}{2}$ feet; and the force of gravity at the surface of the earth $= 1$.

The velocity acquired by a body in falling through $\frac{1}{2}r$, by the force of gravity, will be $=$ the velocity with which a body may describe a circle at the distance AC; therefore

$$\sqrt{m} : \sqrt{\frac{r}{2}} :: 2m : \frac{2m}{\sqrt{m}} \times \sqrt{\frac{r}{2}} = \sqrt{(2mr)} = \text{the velocity in the circle ADB per second.}$$

Let n be the number of feet in the circumference of the earth, then $\sqrt{(2mr)} : n :: 1 : n \div \sqrt{(2mr)} = \text{period. time in the circle ADB}$, which put $= p$. Let P be the period. time of the earth's revolution, and since C, the centrifugal force, is as $\frac{r}{p^2}$, and r is here

given, C is as $\frac{1}{p^2}$, $P^2 : p^2 :: 1 : p^2 \div P^2 = a$, the centrifugal force at A. Again (if $x = \text{dist. CF}$) since C is as $\frac{x}{p^2}$, and p is given, C is as x , and therefore $r : x :: 1 : \frac{x}{r} = \text{the centripetal force}$

force at F; also $r : x :: a : \frac{ax}{r}$ = the centrifugal force at F,

whence the effective force tending to the centre C = $\frac{x}{r} - \frac{ax}{r}$

$= \frac{x}{r} \times (1-a) = x \times \frac{1-a}{r} = F$. Now, from the general equation, $F \cdot i = v \cdot v$, we may derive a value for v in terms of x , for by substitution, $x \cdot i \times \frac{1-a}{r} = v \cdot v$, and $x^2 \times \frac{1-a}{r} = v^2$;

and therefore $v = x \sqrt{\frac{1-a}{r}}$: whence v is as x , and therefore the spiral is the logarithmic one.

XXIV. QUESTION 264, answered by Mr. Lowry.

Pl. 30, Fig. 602. Let A, B be the given points, EF the given chord, and O the centre of the given circle. About the centre O describe a circle to touch EF at G, then OG being drawn will be \perp to EF, and of a given length; suppose the \perp s AC, BD to be drawn as required. Then,

First. *When the ratio of BD to AC is given.*

Let EF and BA be produced till they meet at H.

Because $AC : BD :: AH : AB$, it follows, by division, that the ratio of $AH : AB$ is given, and AB is given in magnitude, therefore AH is given, and H is a given point. Consequently if HEF be drawn to touch the circle at H, the thing is done.

Secondly. *When the sum or difference of AC and BD are given.*

These cases are constructed generally at Article 28, Vol. I. of the Repository, and a reference to that article is all that is necessary in this place.

Thirdly. *When the rectangle $BD \cdot AC$ is given.*

Through the centre O draw IOS parallel to EF, meeting AC in I, and BD in S; join AO and draw OK \perp to AB, KT \perp to OI, KL \perp to AO, and AV \perp to KT. Then $BD = BS + OG$ and $AC = AI + OG$, therefore $BD \cdot AC = BS \cdot AI + OG \cdot (BS + AI) + OG^2$, and therefore $BS \cdot AI + OG \cdot (BS + AI) + OG^2$ is equal to a given space, equal, suppose, to $AO \cdot AZ$. Now TK is evidently equal to half the sum of BS, AI, and

KV equal to half their difference; therefore

$BS = TK + KV$, and $AI = TK - KV$; wherefore

$BS \cdot AI = TK^2 - KV^2$ and $TK^2 - KV^2 + 2OG \cdot TK = AO \cdot AZ$, or
 $LO \cdot TK^2 - LO \cdot KV^2 + 2OG \cdot LO \cdot TK = AO \cdot LO \cdot AZ$:

But the triangles AKV , KOT are similar, therefore

$AL : LO :: AK : KT :: KV : TO^2$, or

$LO \cdot KV^2 = AL \cdot TO^2 = AL \cdot (OK^2 - KT^2)$

$= AL \cdot LO \cdot OL - AL \cdot KT^2$, wherefore

$LO \cdot TK^2 + AL \cdot TK^2 \} + 2OG \cdot LO \cdot TK \} = AO \cdot LO \cdot AZ + AL \cdot AO \cdot OL$, or

$AO \cdot TK^2 + 2OG \cdot LO \cdot TK = AO \cdot LO \cdot LZ$,

Make $AO \cdot OQ = 2OG \cdot LO$, then

$AO^2 + TK^2 + AO \cdot OQ \cdot TK = AO \cdot LO \cdot LZ$, or

$TK^2 + OQ \cdot TK = LO \cdot LZ$, therefore TK becomes known by the 29th. VI. of the Elements, (See Playfair's Edition,) and the method of construction is obvious.

Fourthly. When the sum of the squares of BD , AC is given.

$BD^2 + AC^2 = BS^2 + AI^2 + 4OG \cdot KT + 2OG^2$,

therefore $BS^2 + AI^2 + 4OG \cdot KT$ is given:

but $BS = TK + VK$, and $AI = TK - KV$,

therefore $BS^2 + AI^2 = 2TK^2 + 2KV^2$, and consequently

$TK^2 + KV^2 + 2OG \cdot KT$ is given, = (suppose,) to $AO \cdot AM$, that is, $LO \cdot TK^2 + LO \cdot KV^2 + 2OG \cdot LO \cdot KT = AO \cdot AM \cdot LO$.

But by similar triangles,

$AL : LO :: AK : KO :: KV : TO = OK - TK$;

therefore $LO \cdot VK^2 = AL \cdot (OK - TK)$, wherefore

$LO \cdot TK^2 + AL \cdot (OK - TK) \} + 2OG \cdot LO \cdot KT \} = AO \cdot AM \cdot LO$, or

$(LO - AL) \cdot TK^2 + 2OG \cdot LO \cdot KT = AO \cdot AM \cdot LO - AL \cdot KO^2$
 $= AO \cdot LO \cdot LM$.

Make $2OG \cdot LO = (LO - AL) \cdot OX$,

and $LO \cdot LM = (LO - AL) \cdot OY$.

Hence $TK^2 + OX \cdot TK = AO \cdot OY$.

Consequently TK may be determined as before.

Finally. When the difference of the squares of BD , AC is given.

$BD^2 - AC^2 = BS^2 - AI^2 + 2OG \cdot (BS - AI)$

$= 4TK \cdot VK + 4OG \cdot VK$;

But the ratio of OT to VK is given;

therefore $(TK + OG) \cdot OT$ is given;

Draw $RW \perp$ to KO produced at W ; then

$OK : OT :: KR : (TK + OG) : RW$, or

$OK \cdot RW = (TK + OG) \cdot OT$; therefore RW is a given line, and the locus of the point R is a straight line RU drawn parallel to KO . Also the locus of the point T is a semi-circle described on OK ; it is therefore required to draw KR so that the inter-cepted

cepted part TR may be of a given length, which is a solid problem, and may be effected by the Conic Sections, or (much easier) by the conchoidal ruler.

XXV. QUESTION 265, *answered by Mr. Cunliffe, the Proposer.*

Fig. 592, Pl. 30. Let APB represent a position of the chain, and imagine SV to be drawn \perp to the middle of AB, meeting the curve of the chain in V: also let PQ and PR be drawn \perp to SV and AB respectively.

Put $2l = APB$ the given length of the chain, or $l = APV$, $m =$ the length of the part PV, $SV = b$, $AR = x$, $RP = SQ = y$; also let a denote the tension of the chain at V when in the position AVB.

Then $VQ = b - y$, and by the property of the curve,

$$a = \frac{m^2 - (b - y)^2}{2(b - y)} = \frac{l^2 - b^2}{2b}, \text{ whence } bm^2 + b^2y - by^2 = bl^2 - l^2y,$$

which being properly ordered gives

$$b = \frac{l^2 + y^2 - m^2}{2y} - \frac{\sqrt{\{(l^2 - y^2) - 2m^2(l^2 + y^2) + m^4\}}}{2y}.$$

Again, by the property of the curve,

$$AS = a \times \text{h.l.} \left(\frac{AV + SV}{AV - SV} \right) = a \times \text{h.l.} \left(\frac{l + b}{l - b} \right), \text{ and}$$

$$PQ = RS = a \times \text{h.l.} \left(\frac{PV + QV}{PV - QV} \right) = a \times \text{h.l.} \left(\frac{m + b - y}{m + y - b} \right); \text{ whence}$$

$$AS - RS = AR = x = a \times \left\{ \text{h.l.} \left(\frac{l + b}{l - b} \right) - \text{h.l.} \left(\frac{m + b - y}{m + y - b} \right) \right\}$$

$$= a \times \text{h.l.} \left(\frac{(l + b) \times (m + y - b)}{(l - b) \times (m + b - y)} \right)$$

$$= \frac{l^2 - b^2}{2b} \times \text{h.l.} \left(\frac{(l + b) \times (m + y - b)}{(l - b) \times (m + b - y)} \right)$$

by substituting for a its equal $\frac{l^2 - b^2}{2b}$.

And exterminating b from this equation by means of its value found above, there will be had an equation expressing the nature of the

the curve, which is the locus of the point P, in terms of its own abscissa and ordinate.

The area of the curve may be generally expressed by series.

XXVI. QUESTION 266, *answered by Mr. Lowry.*

Plate 30, Fig. 593, 594. **ANALYSIS.** Suppose it done, and let A and O be the centres of the given circles, B the given point in the line joining their centres, D the point of contact, and C the centre of the required circle. Draw CA and CB; then CA will pass through D, the point of contact, and CD will be $= CB$. Therefore $AC + CB = AD$ in fig. 593, and $AC - CB = AD$ in fig. 594, $=$ to a given line.

Draw the radius CO, then (Stewart's General Theorems, Prop. II.) AC^2 together with the space to which BC^2 has the same ratio that BO has to AO , is equal to the rectangle BAO together with the space to which CO^2 has the same ratio that BO has to AB , that is equal to a given space, equal to P^2 .

Therefore the problem is reduced to the following, viz. Given the sum or difference of two lines to determine them, when the square of one, together with the space to which the square of the other has a given ratio, is equal to a given space; which may be effected as follows:

Take $ad =$ the given sum or difference (see fig. 595 and 596), and on ad (produced when the difference is given) take any point b and erect the perpendicular bg so that $db^2 : bg^2$ in the given ratio of $BO : AO$; draw dg and from a apply $am =$ to P ; draw also $mc \perp$ to ad ; so shall ac, cd be the two lines required; that is, if AC be made $= ac$, the point C will be determined.

For cm^2 is evidently the space to which cd^2 or CB^2 has the same ratio that BO has to AO , and $ac^2 + cm^2 = AC^2 + cm^2 = P^2 =$ the given space.

XXVII. QUESTION 267, *answered by Mr. Lowry, the Proposer.*

Plate 30, Fig 597. **CONSTRUCTION.** Bisect the given base AB at D, and draw $DO \perp$ to AB , and such that DO may be to DB in the given ratio; on DO describe a semi-circle, and therein apply $DC = DB$; join AC, BC , and ACB is the Δ required.

About the centre, with the distance OCO , describe a circle cutting DO produced in E and F. Then we shall prove,

1st. That the circle ECF is the locus of the vertices of all the

Δ s constituted on the base AB when the sum of the squares of the sides has to the area of the Δ the ratio of $4OD$ to DB .

2ndly. That C is the point in the circumference ECF where the ratio of AC to BC is the greatest possible.

Let C' be any point in the circumference; join AC', BC', OC', and DC', and draw CH parallel, and C'G perpendicular to AB. Then

$$OD^2 - DB^2 = OC^2 \text{ or } C'O^2 = CH^2 + HO^2, \text{ or}$$

$$OD^2 - OH^2 (= 2OH \cdot HD + HD^2) = CH^2 + DB^2,$$

and adding HD^2 to each,

$$2OD \cdot HD = CH^2 + DB^2 + HD^2 = DB^2 + C'D^2; \text{ therefore}$$

$$4OD \cdot HD = 2DB^2 + 2C'D^2 = CA^2 + CB^2. \text{ Consequently}$$

$$CA^2 + CB^2 (4OD \cdot HD) : \text{area of the } \Delta AC'B (BD \cdot DH) :: 4OD : DB.$$

And if the points C' and C coincide

$$AC^2 + BC^2 : \text{area } \Delta ACB :: 4OD : DB, \text{ that is, in the given ratio.}$$

Again, produce OC to meet AB produced in S, then since $AD = DB = DC$, and the $\angle DCS$ a right one, CS is a tangent to the circle which passes through the points A, C, B. With the centre S, and distance SC describe a circle, cutting BC', in C, and join AC.

Then $SC^2 = BS \cdot SA$, and by a well known proposition

$$AC : CB :: AC : PC; \text{ but }$$

the ratio of $AC : PC$ is evidently greater than that of $AC : CB$; therefore the ratio of $AC : CB$ is greater than that of $AC' : BC'$.

The triangle ACB is right angled at C.

XXVIII. QUESTION 268, *answered by Mr. Lowry.*

Plate 30, Fig. 598. CONSTRUCTION. On the given line AD describe a segment of a circle to contain an angle equal to half the given vertical angle. At A draw a tangent AI of such a length that its square may be equal to the given difference. Through the point I describe a circle concentric with the other, and from B, the extremity of the diameter drawn perpendicular to AD, draw BC to make the $\angle BCA =$ the given one; shall ACB be the Δ required.

Take CF = BC, and join BF, DE, and from B draw the tangent BH. Then since CF = BC, AF is equal to the sum of the sides of the Δ ACB, and the $\angle CFB = CBF =$ half the vertical $\angle ACB$, =, by construction, to the $\angle AED$, and the $\angle EAD$ is common to the Δ s ABF, ADE; therefore they are similar, and

$$AD \times AF = AE \times AB: \text{ but,}$$

$$AI^2 = BH^2 = BE \times AB; \text{ therefore}$$

$$AD \times AF + AI^2 = AE \times AB + BE \times AB = AB^2.$$

Therefore

Therefore the square of the base exceeds the rectangle under the sum of the sides and a given line, by the given difference.

The perpendicular BK is evidently the greatest that can be inscribed in the circle when it passes through the centre, and therefore in this case must be the greatest possible.

**XXIX. QUESTION 269, answered by Mr. Lowry,
the Proposer.**

This problem admits of three cases according to the situation of the given points with respect to circle; viz.

1st. When the given points are without the circle.

2ndly. When two of them are within, and the remaining one without the circle; and

3rdly. When one of the points is within and the other two without the circle.

The construction for the first case is as follows. Fig. 599, Pl. 30.

Let A, B, C, be the three given points, KHL M the circle in which the trapezium is to be inscribed, and IS the other given circle. Draw the tangents AD, BE, and in AB assume the point F (on the same side of A with the point C) so that the rectangle CAF = AD², and in AB find the point G (on the same side of B with the point F) so that the rectangle GBF = BE²; draw GM to touch the given circle IS at I, also draw CM meeting the circle at K, AK meeting the circle at H, BH meeting the circle at L, join LM, and HKLM is the trapezium required.

Again, for the 2nd and 3rd Cases. Fig. 600, 601, Pl. 30.

In AB assume the point F so that the rectangle CAF = AD², and the point G so that the rectangle GBF = PBQ; draw GM to touch the given circle IS at I, also draw CM meeting the circle at K, AK meeting the circle at H, BH meeting the circle at L, join LM, and HKLM is the trapezium required.

For, by Prop. XLV. and XLVI. Lib. I. of Dr. Stewart's *Propositiones Geometricæ*, the points L, M, G are in a straight line, therefore the sides HK, KL, and KM pass through the given points A, B, C, respectively, and the side ML touches the given circle.

Q. E. D.

XXX.

XXX. Or, PRIZE QUESTION 270, *answered by the Poser, Philalethes Cantabrigiensis.*

In printing this question, the fine + was put instead of the fine — before the term $2\sqrt[3]{x}$, (as was noticed on the cover of No. XII.) which will occasion a great difference in the value of y , and incumber the numerical calculation with decimals, but the method of solution will be nearly the same. I shall therefore give a solution to the question as it was written.

By Madam AGNESI's *Analytical Institutions*,* Vol II, Book III, Sect. I, Article 55, put $u^6 = x$; then we shall have

$\frac{6uu^5}{(1 - 2u^6 + u^8)^2} = y$; and, since the denominator of this fraction

is the product of

$(1 + u - uu^6)^2 \times (1 - u)^8$, we shall have by Art. 62 of the same Section of the book before mentioned,

$$\frac{6uu^5}{(1 - 2u^6 + u^8)^2} = \left\{ \begin{array}{l} \frac{36u + 102uu + 48uu^6 - 86u^8}{(1 + u - uu^6)^2} \\ + \frac{-36u + 42uu}{(1 - u)^8} \end{array} \right.$$

Now the fraction $\frac{-36u + 42uu}{(1 - u)^8}$ is evidently equal to these two

fractions, $\frac{6u}{(1 - u)^4} - \frac{42uu}{1 - u}$,

the fluents of which are $\frac{6}{1 - u} + 42 \times \text{h. l. } (1 - u)$.

And, since $(1 + u - uu^6)^2$ is the product of

$(\frac{1 + \sqrt{5}}{2} - u)^8 \times (\frac{-1 + \sqrt{5}}{2} + u)^8$, the other fraction

on the right-hand side of the above equation may be resolved into four fractions, of which the fluents will be two algebraic quantities and two logarithms.

* An English Translation of this valuable work was made by the late Professor COLSON, of Cambridge, and just published from the Translator's Manuscript, under the inspection of the Rev. JOHN HELLINS, B.D. F. R. S.

But

But an easier way of obtaining the fluent of the fraction

$\frac{36u + 102uu + 48u^2 - 36u^3}{(1+u-uu)^2}$ is, to assume it =

$$\frac{A+Bu}{1+u-uu} + C \times \text{h. l. } (1+u-uu) + D \times \text{h. l. } \left(\frac{1+\sqrt{5}}{2} - u \right),$$

and to put the fluxion of this expression = the given fluxion; from which the values of A, B, C, and D will be easily obtained; viz.

$$\begin{aligned} A &= 21.6, & C &= 0.246315 \\ B &= 34.8, & D &= -36.492629 \end{aligned}$$

Now collecting these fluents together we have

$$\begin{cases} \frac{A+Bu}{1+u-uu} + C \times \text{h. l. } (1+u-uu) \\ + D \times \text{h. l. } \left(\frac{1+\sqrt{5}}{2} - u \right) + \frac{6}{1-u} + 42 \times \text{h. l. } (1-u), \end{cases}$$

the sum of which quantities, when $u = 0$, is

$$A + D \times \text{h. l. } \left(\frac{1+\sqrt{5}}{2} \right) + 6. \text{ Therefore as } x, y, \text{ and } u$$

vanish together, from the sum of the fluents above found the constant quantities

$$A + D \times \text{h. l. } \left(\frac{1+\sqrt{5}}{2} \right) + 6 \text{ must be subtracted and we shall}$$

have

$$y = \begin{cases} \frac{A+Bu}{1+u-uu} + C \times \text{h. l. } (1-u-uu) \\ + D \times \text{h. l. } \left(\frac{1+\sqrt{5}}{1+\sqrt{5}-2u} \right) + \frac{6}{1-u} \\ + 42 \times \text{h. l. } (1-u) - A - 6; \end{cases}$$

in which expression $\text{h. l. } \left(\frac{1+\sqrt{5}}{1+\sqrt{5}-2u} \right)$ is put for its equal

$$- \text{h. l. } \left(\frac{1+\sqrt{5}}{2} - u \right) + \text{h. l. } \left(\frac{1+\sqrt{5}}{2} \right).$$

And the numerical values of the several terms, when $u = \sqrt{\frac{9}{10}}$ (if my calculation be correct,) are as below; viz.

A +

$$\frac{A+Bu}{1+u-uu} = 54.85600, \quad 42 \times h.l. (1-u) = -170.13756,$$

$$Cx h.l. (1+u-uu) = 0.00418, \quad -A - 6 = -27.6$$

$$-D \times h.l. \left(\frac{1+\sqrt{5}}{1+\sqrt{5-2u}} \right) = 34.10775, \quad \text{The sum} = 197.73756$$

$$\frac{6}{1-u} = 344.69287,$$

$$\begin{array}{r} \text{The sum } 433.66080 \\ - 197.73756 \\ \hline \end{array}$$

$$\text{Diff. of the sums } 235.92324 = y, \text{ which was required.}$$

The Method of solving this question, as it was printed, by I. H.

Using the notation in the proposers solution, (which I have seen) we have

$\frac{6iu^5}{(1+2u+u^3)^5} = y$, of which fraction the denominator is the product of $(0.4533977 - 0.2055694 u + u^3)^5 \times (2.2055694 + u)^5$; and therefore, (putting $2.2055694 = a$, for the sake of brevity,) by Art. 62 of the first section of the book above referred to, we may assume

$$\left. \begin{array}{l} \frac{Au + Buu + Cuu^2 + Duu^3}{(\frac{1}{a} - \frac{u}{aa} + uu)^5} \\ + \frac{Euu + Fuu^2}{(a+u)^5} \end{array} \right\} = \frac{6iu^5}{(1+2u+u^3)^5}$$

from which equation the values of A, B, C, &c. will be had; and then, to find the fluent of

$\frac{Au + Buu + Cuu^2 + Duu^3}{(\frac{1}{a} - \frac{u}{aa} + uu)^5}$, (which is the only difficulty that

$$(\frac{1}{a} - \frac{u}{aa} + uu)^5$$

remains), assume it =

$$\frac{G + Hu}{\frac{1}{a} - \frac{u}{aa} + uu} + I \times h.l. \left(\frac{1}{a} - \frac{u}{aa} + uu \right)$$

+ K

+ K \times circ. arch whose rad. is $\frac{\sqrt{4a^3-1}}{2aa}$ and tang. $u = \frac{1}{2aa}$,

and put the fluxion of this expression = the given fluxion, by which means G, H, &c. will be determined. (See Art. 40, of the first section of the book before referred to).

The fraction $\frac{E\dot{u} + F\dot{u}u}{(a+u)^2}$ is = $\frac{(E-aF)\dot{u}}{(a+u)^2} + \frac{Fu}{a+u}$

Now, collecting these fluents together, and correcting them, we have

$$y = \left\{ \begin{array}{l} \frac{G + Hu}{\frac{1}{a} - \frac{u}{aa} + uu} - aG \\ + I \times \left\{ h.l. \left(\frac{1}{a} - \frac{u}{aa} + uu \right) + h.l. a \right\} \\ + K \times \left\{ \begin{array}{l} \text{circ. arch of tang. } u = \frac{1}{2aa} \\ + \text{circ. arch of tang. } \frac{1}{2aa} \end{array} \right\} \frac{\sqrt{4a^3-1}}{2aa} \text{ and radius} \\ + \frac{aF - E}{a+u} - F + F \times \left\{ h.l. (a+u) - h.l. a \right\} \end{array} \right.$$

N. B. In this problem $\frac{\sqrt{4a^3-1}}{2aa}$ is = $\frac{\sqrt{8aa+3}}{2a}$.

The same, answered by Mr. Cunliffe.

Put $v^6 = x$, and the equation will become $\frac{6\dot{v}^5}{(1-2v^3+v^6)^2} = y$.

Now it is pretty obvious that $(1-v) \times (1+v-v^3) = 1-2v^3+v^6$: therefore assume

$\frac{Av+B}{(1-v)^2} + \frac{Cv^3+Dv^6+Ev+F}{(1+v-v^3)^2} = \frac{v^5}{(1-2v^3+v^6)^2}$, by reducing the terms to a common denominator, &c. there will be had

$$\left. \begin{array}{l} (A+C-1)v^5 + \left\{ B+D-2(A+C) \right\} v^4 \\ + \left\{ E+C-A-2(B+D) \right\} v^3 + (2A-B+F-2E+D)v^2 \\ + (A+2B-2F+E)v + B+F \end{array} \right\} = 0.$$

Making the coefficients of the homologous terms = 0, we have,
after proper reduction,
 $A = 7, B = -6, C = -6, D = 8, E = 17$ and $F = 6$.
Wherefore,

$$\frac{Av+B}{(1-v)^4} + \frac{Cv^2+Dv^3+Ev^4+F}{(1+v-v^4)^4} = \frac{7v-6}{(1-v)^4} + \frac{6+17v+8v^4-6v^8}{(1+v-v^4)^4}.$$

Consequently the fluent of $\frac{v^4v}{(1-2v^4+v^8)}$ = fluent of $\frac{7vv-6v}{(1-v)^4}$ + flu. $\frac{6v+17vv+8v^4v-6v^8v}{(1+v-v^4)^4}$

$$= \frac{\frac{1}{1-v} + 7 \times \text{h.l.}(1-v)}{1+v-v^4} + \text{flu.} \frac{6v+17vv+8v^4v-6v^8v}{(1+v-v^4)^4}$$

Now $\frac{6v+17vv+8v^4v-6v^8v}{(1+v-v^4)^4} = \frac{6vv-2v}{1+v-v^4} + \frac{13vv+8v}{(1+v-v^4)^4}$ by \div .

But the denominators of these fractions will be more simple by taking away the second term; it will also be more obvious to which of the tabular forms the fluents of the several terms belong.

In order to take away the said second term of the denominators, put $z + \frac{1}{4} = v$, then will

$$\begin{aligned} \frac{6v+17vv+8v^4v-6v^8v}{(1+v-v^4)^4} &= \frac{6vv-2v}{1+v-v^4} + \frac{13vv+8v}{(1+v-v^4)^4} \\ &= \frac{6zz}{\frac{5}{4}-z^2} + \frac{z}{\frac{5}{4}-z^2} + \frac{13zz+14\frac{1}{4}z}{(\frac{5}{4}-z^2)^4} \\ &= \frac{6zz}{\frac{5}{4}-z^2} + \frac{13zz+14\frac{1}{4}z+z(\frac{5}{4}-z^2)}{(\frac{5}{4}-z^2)^4} \\ &= \frac{6zz}{\frac{5}{4}-z^2} + \frac{15\frac{1}{4}z+13zz-z^2z}{(\frac{5}{4}-z^2)^4}. \end{aligned}$$

The fluent of the first term, viz. $\frac{6zz}{\frac{5}{4}-z^2}$ is $-3 \times \text{h.l.}(\frac{5}{4}-z^2)$.

Assume $\frac{Mz+N}{\frac{5}{4}-z^2} + Q \times \text{flu.} \frac{z}{\frac{5}{4}-z^2} = \text{flu. of} \frac{15\frac{1}{4}z+13zz-z^2z}{(\frac{5}{4}-z^2)^4}$;

which expression put into fluxions is

$$\frac{Mz(\frac{5}{4}-z^2)+2zz(Mz+N)}{(\frac{5}{4}-z^2)^2} + Qz(\frac{5}{4}-z^2) = \frac{15\frac{1}{4}z+13zz-z^2z}{(\frac{5}{4}-z^2)^4};$$

dividing by $\frac{z}{(\frac{5}{4}-z^2)^2}$, and expanding the result there will

be had $(M - Q) z^3 + 2Nz + \frac{1}{4}(M + Q) = 15z^3 + 13z - z^2$,
 or $(M + 1 - Q) z^3 + (2N - 13)z + \frac{1}{4}(M + Q) - 15z^3 = 0$.

Making the co-efficients of the homologous terms = 0, there will be had, after proper reduction,

$M = \frac{29}{5}$, $N = \frac{13}{2}$ and $Q = \frac{34}{5}$. Therefore the fluent of

$$\frac{15z^3 + 13z - z^2}{(\frac{5}{4} - z^2)^2} = \frac{\frac{29}{5}z + \frac{13}{2}}{\frac{5}{4} - z^2} + \frac{34}{5} \times \text{flu. } \frac{z}{\frac{5}{4} - z^2}$$

$$= \frac{\frac{29}{5}z + \frac{13}{2}}{\frac{5}{4} - z^2} + \frac{34\sqrt{5}}{25} \times \text{h.l.} \left(\frac{\frac{\sqrt{5} + z}{2}}{\frac{\sqrt{5} - z}{2}} \right),$$

because the fluent of $\frac{z}{\frac{5}{4} - z^2} = \frac{1}{\sqrt{5}} \times \text{h.l.} \left(\frac{\frac{\sqrt{5} + z}{2}}{\frac{\sqrt{5} - z}{2}} \right)$.

Consequently the fluent of

$$\frac{6v + 17vv + 8v^2v - 6v^3v}{(1 + v - v^2)^2} = \left\{ \begin{array}{l} \frac{\frac{29}{5}z + \frac{13}{2}}{\frac{5}{4} - z^2} + \frac{34\sqrt{5}}{25} \times \text{h.l.} \left(\frac{\frac{\sqrt{5} + z}{2}}{\frac{\sqrt{5} - z}{2}} \right) \\ \frac{5}{4} - z^2 \\ - 3 \times \text{h.l.} \left(\frac{5}{4} - z^2 \right) \end{array} \right.$$

$$= \left\{ \begin{array}{l} \frac{\frac{29}{5}v + \frac{13}{2}}{5(1 + v - v^2)} + \frac{34\sqrt{5}}{25} \times \text{h.l.} \left(\frac{\frac{\sqrt{5} + v}{2}}{\frac{\sqrt{5} - v}{2}} \right) \\ - 3 \times \text{h.l.} (1 + v - v^2), \end{array} \right.$$

by restoring the value of z .

Therefore the fluent of

$$\frac{v^3v}{(1 - 2v^2 + v^3)^2} = \frac{1}{1 - v} + 7 \times \text{h.l.} (1 - v) + \text{flu. } \frac{6v + 17vv + 8v^2v - 6v^3v}{(1 + v - v^2)^2}$$

O_2

=

$$= \left\{ \begin{array}{l} \frac{1}{1-v} + 7 \times \text{h.l.}(1-v) + \frac{29v+18}{5(1+v-v^2)} \\ + \frac{34\sqrt{5}}{25} \times \text{h.l.} \left(\frac{\frac{\sqrt{5-1}}{2} + v}{\frac{\sqrt{5+1}}{2} - v} \right) - 3 \times \text{h.l.}(+v-v^2). \end{array} \right.$$

But by the question this expression ought to vanish when $v = 0$; therefore the correct fluent of

$$\left. \begin{array}{l} \frac{v^5 y}{(1-2v^2+v^3)^2} \\ = \frac{y}{6} \end{array} \right\} = \left\{ \begin{array}{l} \frac{1}{1-v} + 7 \times \text{h.l.}(1-v) + \frac{29v+18}{5(1+v-v^2)} \\ + \frac{34\sqrt{5}}{25} \times \text{h.l.} \frac{\frac{\sqrt{5-1}}{2} + v}{\frac{\sqrt{5+1}}{2} - v} + \text{h.l.} \left(\frac{\sqrt{5+1}}{\sqrt{5-1}} \right) \\ - 3 \times \text{h.l.}(1+v-v^2) - \frac{23}{5} \end{array} \right\} \\ = 39.3204703, \text{ because } v = \sqrt[6]{x} = \sqrt[6]{\frac{9}{10}} = \\ 0.982593175.$$

Whence $y = 6 \times (39.3204703) = 235.9228218.$

W. W. R.

J. H. is requested to send to Mr. Glendinning's for the Medal for solving the Prize Question.

MATHEMATICAL QUESTIONS.

To be answered in Number XV.

I. QUESTION 301, *by Mr. William Francis, Teacher of the Mathematics, Maidenhead, Berks.*

An octagon of fertile soil,
Whose copious bounds were just a mile,
Was let unto a baker
Who, fifty years, did pay no rent ;
What can be due at *five per cent.**
And just two pounds per acre?

* *Compound Interest.*

II. QUESTION 302, *by Master John Golding, at Mr. Gregory's Academy, Cambridge.*

What is the axis of a globe when the superficies and solidity are each expressed by the same number? 2nd. What is the superficies when the axis and solidity are each expressed by the same number? 3d. What is the solidity when the axis and superficies are each expressed by the same number?

III. QUESTION 303, *by Mr. Francis.*

Required the length of a very thin rectangular plate of brass, 2 inches wide, that would exactly reach from the bottom diagonally across to the top of a cylindrical ale quart, whose diameter is $\frac{1}{4}$ inches.

IV. QUESTION 304, *by the late Mr. John Watts, of Auber-
bourn, Wilts.*

Two poles were placed upright in the earth at 10 yards distance from each other to which a rope was fastened 5 yards above the ground, but a heavy weight being fixed to the middle thereof depressed the rope two yards lower in that point and caused the poles to meet at the upper end. Query their length?

V. QUESTION 305, by Mr. John Whitley.

Given $\begin{cases} x + y = s \text{ (2)} \\ x^2 + y^2 = b \text{ (32)} \end{cases}$ to find x and y
by quadratics?

VI. QUESTION 306, by Mr. John Barron, Spilby.

There is an air pump, the capacity of its receiver is to that of the barrel as 9 to 2. Now it is required to determine how many strokes of the piston will rarify the air in the receiver to the same density as the atmosphere, at the altitude of 30 miles, when the density at the surface is 1?

VII. QUESTION 307, by Mr. Francis.

A gentleman having a quadrilateral garden ABCD, right-angled at A, wishes to render it more uniform by producing the side AD to E, which is also to be a right-angle, and so situated that the \triangle DEC may be equal to the \triangle ADB, formed by the two sides AB, AD, and the diagonal line BD. Now the front door of his house, F, is equally distant from B and C, whose distance is the same, or 60 yards, from each other; moreover the lines BD, DC, and DF, are to each other as 9, 12, and 8 respectively. Hence the figure and area of the garden are required?

VIII. QUESTION 308, by Tyro Philomatheticus.

An elliptical field, the sum of the diameters of which is 1000 yards, is to be sold at half a guinea for every yard in length on the transverse, and a guinea for every yard in length on the conjugate; required the dimensions and area of the field, supposing it of the most advantageous form for the purchaser?

IX. QUESTION 309, by Mr. Francis.

M. G rnerin's balloon appears to be composed of a cylinder, whose ends are covered with two hemispheres. Now its diameter being 24 and length 40 feet, what quantity of silk was required to make it? with what weight would it ascend, admitting it to be filled with air 13 times lighter than atmospheric air, and what was the length of the parabolic tract described in his journey from Lord's ground, supposing his greatest elevation to have been 3000 yards, and the distance of the places whence he ascended and where he alighted 10 miles in a direct line?

X.

X. QUESTION 310, by Mr. Thornoby.

Required the manner of valuing recurring surds continued *ad infinitum*, or to shew the manner of finding an equation by which their value may be found? and apply the method to the following

$$1st. \sqrt{a + \frac{b}{\sqrt{a + \frac{b}{\sqrt{a + \frac{b}{\sqrt{a + \frac{b}{\sqrt{a + \frac{b}{\sqrt{a + \frac{b}{\sqrt{a + \text{ &c.}}}}}}}}}}}}}$$

$$2nd. \sqrt{a + \frac{b}{\sqrt{c + \frac{d}{\sqrt{a + \frac{b}{\sqrt{c + \frac{d}{\sqrt{a + \frac{b}{\sqrt{c + \frac{d}{\sqrt{a + \frac{b}{\sqrt{c + \text{ &c.}}}}}}}}}}}}}}$$

$$3rd. \sqrt{\frac{a}{b + \sqrt{a + \frac{b + \sqrt{a + \text{ &c.}}}}}}}}}}}}}$$

XI. QUESTION 311, by Mr. Gregory, Cambridge.

There is a sphere whose diameter is 12 inches; what is the side of its inscribed cube; and what is the difference between the solidity of the greatest inscribed octagonal pyramid which can be inscribed in the cube, and that of the greatest circular spindle which can be inscribed in either of the six spaces between the cube and the sphere.

XII. QUESTION 312, *by Mr. William Peacock.*

A Gentleman has a garden bounded by a semicircle FCD, and a semi-parabola FCAB, F being the vertex thereof. Now FB the abscissa of the parabola, (or diameter of the semicircle,) and AB the ordinate (rightly applied) being given, the former 100 and the latter 45 yards ; it is required to find the length of the longest walk CD that can be made in the garden, parallel to AB.

XIII. QUESTION 313, *by Mr. I. H. Swale.*

B is a given point in the circumference of a circle given in magnitude and position, and P another given point, either within or without the circle ; it is required to draw PAC, meeting the circle in A and C, so that if AB, CB be drawn, the sum of their squares may be equal to a given space.

XIV. QUESTION 314, *by Mr. W. Rochester.*

Having given, as in question 235 (vide No. X.), it is required to solve the problem when the sum of the squares of the perpendiculars is equal to a given space.

XV. QUESTION 315, *by Limenus, of Bruton, Somerset.*

Let E be the centre of a circle inscribed in the triangle ABC, which let meet the base A B in a ; make Bb = Aa, and E M, drawn parallel to C b will bisect the base in M. Required a demonstration ?

XVI. QUESTION 316, *by Mr. William Ticken, of the Royal Military College, Great Marlow, Bucks.*

At what part of the earth is the twilight absolutely a minimum, on October 12th ? and how much is the twilight shorter there than it is in the latitude $52^{\circ} 12' N.$ on the same day ?

XVII. QUESTION 317, *by Mr. Nicholas Bottom.*

In a given triangle to inscribe the greatest ellipsis possible.

XVIII.

XVIII. QUESTION 318, *by Quid Nunc,*
From Bonnycastle's Algebra.

To find two whole numbers such, that, if unity be added to either, or to their sum or difference, the sums thence arising shall be all square numbers.

XIX. QUESTION 319, *by Mr. Bosworth, Cambridge.*

When the sun shines upon a right cone standing with its base upon a horizontal plane, the shadow of the cone will be bounded by lines drawn from the vertex of the shadow as tangents to the base of the cone. Required a demonstration?

XX. QUESTION 320, *by Mr. Johnson, Birmingham.*

Given the difference of the segments of the base made by the perpendicular, the ratio which the sum of the squares of the sides has to the rectangle contained by the perpendicular and a given line, to construct the triangle when the sum of the base and perpendicular is a maximum.

XXI. QUESTION 321, *by Mr. John Whitley.*

If Q be the point in the triangle, from which perpendiculars are drawn to the sides, so that the solid contained under them is the greatest possible; three times the sum of the squares of the lines drawn from Q to the angular points of the triangle is equal to the sum of the squares of the sides of the triangle.

XXII. QUESTION 322, *by Mr. I. F.*

If ABCD be a circle given in magnitude and position, and if P be a given point without the same, a point Q may be found, within the circle, such, that if any line whatever be drawn through P meeting the circle in C and D, and CQ, DQ be joined, the rectangle CQ \times QD shall be equal to a certain given space.

XXIII. QUESTION 323, *by Mr. John Lowry.*

Let ABC be a triangle inscribed in the circle AFCBQ, whose centre is O, FDQ a diameter drawn perpendicular to the base, and meeting it in D, and let CE be drawn parallel to the base AB, and meeting DF in E. I say the solid contained by the square of the

the difference of the sides, and the line drawn from the vertex to the middle of the base, will be a maximum, when the square of DF (that part of the diameter above the base) is equal to thrice the rectangle DO \times EF. Required the demonstration?

XXIV. QUESTION 324, by Limenus, Bruton.

Join A, B, any two points in a conic section; bisect AB in C, and draw MN parallel to it, and terminated by the curve; draw MC_n and NC_n to the section, and the concourse of M_n and N_n will give the point P, from whence PA, PB, being drawn will touch the curve. Required a demonstration?

XXV. QUESTION 325, by Mr. John Lowry.

Given the difference of the segments of the base, the excess of the square of one side above the space to which the square of the other side has a given ratio, to construct the triangle when the solid contained by the square of the perpendicular and the base is a maximum.

XXVI. QUESTION 326, by Marlovienfis.

Required a simple finite expression for the sum of a slowly converging series of this form,

$a + bx + cx^2 + dx^3 + ex^4 + \&c. ad infinitum$; in which all the terms are positive, or added to each other.

It is remarkable that this series, which admits of perfect summation, is not to be found in any of the Analytic Writers, *De Moivre*, *Waring*, *Landen*, &c. Nor even in *Clarke's Summation of Series*; though the latter Treatise contains many forms that lead immediately to it.

XXVII. QUESTION 327, by Mr. James Cunliffe.

It is required to exhibit the whole area of the curve which is the *locus* of the middle point V, of the chain, independant of series, from the coincidence of the points A and B, to the time that the chain becomes completely stretched along the horizontal line AB. See my solution to question 265.

XXVIII.

XXVIII. QUESTION 328, *by Philalethes Cantabrigiensis.*

If a ball of lead 10 inches in diameter were suspended at a point by a very slender wire 20. inches in length, and made to vibrate in a vertical plane; and if, at the commencement of the motion, the wire being stretched out tight, should be in a line parallel to the horizon, and the ball in such a position that the wire, if continued, should pass through the centre of it; it is required to determine in what time the wire would first become perpendicular to the horizon?

XXIX. QUESTION 329, *by Marloviensis.*

There is an uniform iron lever ACB, of the second order, the weight of which is 2lb. avoid. *per* inch longitudinally. At C, 36 inches from the fulcrum A, is appended a weight of 100lb. Required what length the lever ought to be, that a power P, applied at the extremity B to raise the weight, may be the least possible?

XXX. PRIZE QUESTION 330, *by Marloviensis.*

In the common cycloid ABC, E and F are two points in the axis BD, equally distant from the middle: from these points lines are drawn parallel to the base, cutting the curve in K and L. The generating circle being described in the situation it would have when it generates the point K, and again when it generates the point L, call the points where these circles touch the base G and H. Now, the axis, and the points E, F, being given, it is required to exhibit, by a concise theorem, the area of the cycloidal space contained within the arcs KG and LH without the aid of fluxions; and also to shew a geometrical method of cutting off a part from the generating circle equal to the same space.

ARTICLE XVI.

Solution to Colonel Titus's Arithmetical Problem.

By James Ivory, Esq.

1. THIS problem requires to find the numbers a , b and c , from the following equations, viz.

$$\left. \begin{array}{l} a^2 + bc = 16 \\ b^2 + ac = 17 \\ c^2 + ab = 18 \end{array} \right\} \dots \text{(No. 1.)}$$

2. Subtract the first of these equations from the second, and the second from the third, and

$$\left. \begin{array}{l} b^2 - a^2 + ac - bc = 1 \\ c^2 - b^2 + ab - ac = 1 \end{array} \right\} \text{ or } \left. \begin{array}{l} (b - a) \times (b + a - c) = 1 \\ (c - b) \times (c + b - a) = 1 \end{array} \right\}$$

$$\text{therefore } b + a - c = \frac{1}{b - a}$$

$$c + b - a = \frac{1}{c - b}$$

Put now, $b - a = m$, $c - b = n$, and we shall have

$$\left. \begin{array}{l} b - a = m \\ c - b = n \\ b + a - c = \frac{1}{m} \\ c + b - a = \frac{1}{n} \end{array} \right\} \dots \text{(No. 2.)}$$

3. From the equations (No. 2.) it is easy to get these values of a , b and c ; viz.

$$\left. \begin{array}{l} a = n + \frac{1}{m} \\ b = \frac{1}{2} \left(\frac{1}{m} + \frac{1}{n} \right) \\ c = \frac{1}{n} - m \end{array} \right\} \dots \text{(No. 3.)}$$

In

In order to get an equation that shall contain only m and n and known numbers, I substitute the values of a , b and c , just found, in one of the original equations (No. 1.) as the first; and I get

$$(n + \frac{1}{m})^2 + \frac{1}{2}(\frac{1}{m} + \frac{1}{n}) \times (\frac{1}{n} - m) = 16.$$

We have still to find another equation that shall contain only m and n ; but from the equations (No. 2) I get, $c - a = m + n$;

and also $ac - ab = \frac{1}{n} - \frac{1}{m}$: therefore $am + an = \frac{1}{n} - \frac{1}{m}$.

We have thus two equations, which are sufficient to determine m and n ; viz.

$$\left. \begin{aligned} (n + \frac{1}{m})^2 + \frac{1}{2}(\frac{1}{m} + \frac{1}{n}) \times (\frac{1}{n} - m) &= 16 \\ am + an &= \frac{1}{n} - \frac{1}{m} \end{aligned} \right\} \text{(No. 4)}$$

and m and n being obtained from these equations the numbers, a , b , and c that are sought will be had by means of the formulae (No. 3).

4. It is not very easy (without a good deal of algebraic process) to deduce from the equations (No. 4) a final equation, containing only one unknown quantity: the shortest way of doing this appears to be the following.

$$(n + \frac{1}{m})^2 = (\frac{mn + 1}{m})^2 = \frac{(mn + 1)^2}{m^2};$$

$$\text{Again, } (\frac{1}{m} + \frac{1}{n}) \cdot (\frac{1}{n} - m) = (\frac{m+n}{mn}) \cdot (\frac{1-mn}{n}) =$$

$$\frac{(m+n) \cdot (1-mn)}{mn^2} = \frac{(m^2 + mn) \cdot (1-mn)}{m^2n^2} \text{ (by multiplying}$$

both numerator and denominator by m).

Therefore, the first of the equations (No. 4) becomes, by substitution, $\frac{(1+mn)^2}{m^2} + \frac{(m^2 + mn) \cdot (1-mn)}{2m^2n^2} = 16$; and, putting $mn = x$, $m^2 = y$; $\frac{(1+x)^2}{y} + \frac{(y+x)(1-x)}{2x^2} = 16$.

Multiply both sides of the second of the equations (No. 4) by m^2n , and it becomes, $am^2n + 2m^2n^2 = m^2 - mn$, or $2xy + 2x^2 = -x + y$.

Thus we have these two equations, viz.

$$\left. \begin{aligned} \frac{(1+x)^6}{y} + \frac{(y+x)(1-x)}{2x^2} &= 16 \\ 2xy + 2x^2 &= -x + y \end{aligned} \right\} \text{(No 5).}$$

In which $x = m$, $y = m^6$.

5. It is now easy to deduce a final equation from the two equations (No. 5); because the unknown quantity y is only simply concerned, without any of its powers.

Multiply the first of the two equations by y , Then $(1+x)^6 + y(y+x) \cdot \frac{1-x}{2x^2} = 16y$: but from the second equation I get $y = \frac{x+2x^2}{1-2x}$; therefore $y+x = \frac{x+2x^2}{1-2x}$
 $+x = \frac{2x}{1-2x}$: therefore, by substitution

$$(1+x)^6 + \frac{1}{2} \cdot \frac{x+2x^2}{1-2x} \times \frac{2x}{1-2x} \times \frac{1-x}{x^2} = 16 \frac{x+2x^2}{1-2x}.$$

which is a final equation and only requires further to be properly reduced to prepare it for resolution.

Omitting the factors common to both numerator and denominator of the second member of the left-hand side, and multiplying all the terms by $(1-2x)^6$ I get

$$(1+x)^6 (1-2x)^6 + (1+2x)(1-x) = 16(x+2x^2)(1-2x)$$

or

$$(1-x-2x^2)^6 + 1+x-2x^2 = 16x-64x^3$$

or

$$2-x-5x^2+4x^3+4x^4 = 16x-64x^3$$

or

$$2-17x-5x^2+68x^3+4x^4 = 0$$

or, multiplying by 4 and transposing

$$8 = 34.2x + 5.4x^2 - 34.8x^3 - 16x^4.$$

And putting $2x = z$

$$8 = 34z + 5z^2 - 34z^3 - z^4.$$

6. Having determined z by the preceding equation we shall have

$$x = \frac{z}{2} \text{ and } y = \frac{x(1+2x)}{1-2x} = \frac{z}{2} \cdot \frac{1+z}{1-z}.$$

Also

Also $mn=x$, $y=m^2$: therefore $m = \sqrt{\frac{z}{2}} \times \sqrt{\frac{1+z}{1-z}}$

and $x = \frac{z}{m} = \sqrt{\frac{z}{2}} \times \sqrt{\frac{1-z}{1+z}}$: Hence

$$a = n + \frac{1}{m} = \left\{ \sqrt{\frac{z}{2}} + \sqrt{\frac{z}{2}} \right\} \times \sqrt{\frac{1-z}{1+z}} = \frac{z-z^3}{2} \times \sqrt{\frac{z}{z-z^3}}$$

$$b = \frac{1}{2} \left\{ \frac{1}{m} + \frac{1}{n} \right\} = \frac{1}{2} \sqrt{\frac{z}{2}} \times \left\{ \sqrt{\frac{1+z}{1-z}} + \sqrt{\frac{1-z}{1+z}} \right\} = \sqrt{\frac{z}{z-z^3}}$$

$$c = \frac{1}{n} - m = \left\{ \sqrt{\frac{z}{2}} - \sqrt{\frac{z}{2}} \right\} \times \sqrt{\frac{1+z}{1-z}} = \frac{z+z^3}{2} \times \sqrt{\frac{z}{z-z^3}}$$

$$\text{or } b = \sqrt{\frac{z}{z-z^3}}$$

$$a = \frac{z-z-z^3}{2} \times b.$$

$$c = \frac{z+z-z^3}{2} \times b.$$

The Arithmetical Problem that is resolved above was of some note in its day. It was first published by Dr. Wallis, in his Algebra, and it was proposed to the Doctor by Colonel Silas Titus, a gentleman of the bedchamber to Charles the Second. Colonel Titus told Dr. Wallis, that the author of the problem was the famous Algebraist Dr. John Pell, who had proposed it to the Colonel.

The Solution of the problem given by Dr. Wallis is remarkably operose and inelegant, Mr. Baron Maseres has lately republished Dr. Wallis's solution (in a Vol. of Tracts on the resolution of Algebraic Equations, printed in 1800) and has been at great pains to set forth all the operations and reasonings with his usual clearness and accuracy. In the same vol. of Tracts there is likewise printed another solution of the same problem by Mr. Frend, which in point of simplicity is preferable to Dr. Wallis's solution.

ARTICLE XVII.

Solution of a question (the 16th, proposed at page 69, Vol. I. but not answered) in this work, by Mr. JOHN FAREY.

To the Editor of the Mathematical Repository.

SIR,

ON the appearance of the *Gentleman's Diary* in November 1789, I was much struck with the assertion of the venerable and profound Mathematician who edited that work, supported by a process attempting to prove, that no part of the weight of a cylinder, circumstanced as in your 16th question Vol. I. p. 69, could be supported by the side of the vessel; and I set about, and produced to my friends, *Mr George Sanderlin*, and others, an investigation of the question (69, *Gent's. Diary*) a copy of which you have below; but still suspending the conclusions of my process, opposed by such high authority; I had recourse to an experiment, the particulars of which you have also below. In a letter soon after to the *Rev. Mr. WILDBORE*, I objected to the principle laid down in the *Diary* for 1790, and recommended an experiment, and having the pleasure of seeing that gentleman in August 1797, at his house in Nottinghamshire, I re-stated my objections, which produced question 753 in the *Diary* for 1798; accident however prevented my sending a solution to that question as I intended, including a solution also to quest. 69. Before closing the present series of your *Repository* it may not therefore be improper to give a place to what follows, in answer to the 16th question therein, which will oblige

Your Obedient Servant,
J. FAREY.

12, *Crown Street, Westminster*,
26th December, 1803.

" On account of the equality of the cylindrical Hoofs, the calculation may without sensible error proceed, as though the cylindrical staff was divided perpendicularly to the axis at the point of immersion: it should also be considered, that the buoyancy of the fluid will be exerted on the centre of gravity of the immersed part, in a *vertical* direction, and since this forms one of the props or supports of the cylinder, the other support i. e. the side of the vessel must, to produce an equilibrium, act in a *vertical* direction also, and hence it is that the inclination of the staff, or height of the side of the vessel, is not a necessary datum, and that if a substitution be made for it, the same will fly off in reducing the equa-

tion, and that the pressure on the side, and the quantity or content of the staff immersed are constant quantities, not affected by the inclination of the staff.

Fig. 655, Pl. 32. Let $AB = l$, represent the staff, immersed in the beer to C , and supported at A by a perpendicular prop; let D be the middle or centre of gravity of the staff, F the middle or centre of gravity of the part without the beer, and E the middle or centre of gravity of the part immersed. Put $AC = y$, $m =$ the weight of an inch in length of the staff, and $n =$ the weight of an inch in length of the cylinder of beer displaced; then $AB \times m = lm$ is the weight of the staff, $BC \times n$ is the weight of the beer displaced $= (l - y) \times n$, which exerts itself upwards at its centre of gravity E , and $DE = AC + CE - AD = y + \frac{l - y}{2} -$

$\frac{1}{2}l = \frac{1}{2}y$. Now if a body at D be supported by two perpendicular props at A and E ; it will be as $DE (\frac{1}{2}y) : AD (\frac{1}{2}l) ::$ pressure at A : pressure at E , and $(DE \times lm) \div (AD + DE) =$ the pressure at $A = (\frac{1}{2}y \times lm) \div (\frac{1}{2}l + \frac{1}{2}y) = lmy \div (l + y)$; also $(AD \times lm) \div (AD + DE) =$ the pressure at $E, = (\frac{1}{2}l \times lm) \div (\frac{1}{2}l + \frac{1}{2}y) = l^2m \div (l + y)$, this in the case of an equilibrium is equal to the action of the fluid, and $l^2m \div (l + y) = (l - y) \times n$, hence $l^2m = (l^2 - y^2) \times n = l^2n - y^2n$, and $ny^2 = l^2 \times (n - m)$, from whence we obtain $y = l \sqrt{(n - m) \div n}$ the length not immersed, $m = n \times (l^2 - y^2) \div l^2$ the weight of an inch in length of the staff, $n = m \times l^2 \div (l^2 - y^2)$ the weight of an inch in length of beer displaced, $l = y \sqrt{n \div (n - m)}$ the staff's length, and by substituting the value of y in $lmy \div (l + y)$ we have $lmy \div n \div (1 + \sqrt{(n - m) \div n}) =$ the pressure on the side of the vessel.

Now in the 16th question $l = 36$ inches, $y = 13$; and the diameter of beer displaced being .75 inch, we have $.75 \times .75 \times .7854 = .4417875$ the content of an inch in length, which drawn into the weight of an inch of beer .5949, gives .2628194 oz. the weight of an inch in length of beer displaced $= n$, and $m = n \times (l^2 - y^2) \div l^2 = .228548$ oz. which drawn into 36 the length of the staff, gives $lm = 8.227719$ oz. the weight of the staff as required. Moreover, $lmy \div (l + y) = 2.182864$ oz. is the weight supported by the side of the vessel, being in this case something more than one fourth part of the whole weight of the staff."

Note. Mr. WILDBORE makes a similar observation to the last, at page 2 of the Diary for 1799, but it is proper to remark that the weight there given, is erroneous, because derived on the

supposition of the vessel bearing no part of the weight. Also that $\frac{m}{n} = .8696$ is the specific gravity of the stuff, beer being 1.

"*Experiment.* I procured a cylinder of light wood, which I painted, and when dry found its length 28.12 inches = l , its mean diameter 1.7 inches, and its weight 17.65 oz. whence $\frac{17.65}{28.12} = .627667$ oz. = m . I fastened a thread to one end thereof, and attached it to one of the scales of a balance, suspended by a pulley over a cistern of water; when the cylinder was immersed and at rest, I put 7.175 oz. into the other scale, which exactly balanced the pull of the thread; after which I lowered and again raised the scales, so that the cylinder passed into all degrees of elevation, and I had the pleasure to observe the scales remain, as nearly as possible in equilibrium, and the thread vertical all the time. I also observed that about 19.5 inches of the cylinder's axis remained above the water at several elevations. When this cylinder was afterwards placed nicely upright in the water, and had sunk to its equilibrium I observed that 13.98 inches were immersed, by which if we divide the cylinder's weight 17.65 we get $n = 1.262581$,

and hence $y = l \sqrt{(n-m)} \div n = 19.94$ inches, the excess of which above 19.5 inches was I believe in some part occasioned by inaccuracy in measuring that length, but more by the inequalities of the cylinder, for on inverting it, the other end sunk 14.45 inches into the water (instead of 13.98) which will give $n = 1.221453$, and $y = 19.61$, much nearer to 19.5 than the above. Further, $lmy \div (l+y) = 7.323$ oz. which differs but .148 of an ounce from the actual tension of the thread."

P. S. 1st. In making the above experiment it was curious to observe, that when the cylinder was placed very nicely upright in the water, it sunk till its whole weight was supported by the fluid, the depth immersed being $ln \div n = 13.98$ inches, when if the cylinder's axis was inclined but ever so little to the vertical line, it suddenly started up out of the water, till only $l - l \sqrt{(n-m)} \div n$ was immersed = about 8.18 inches, and the cylinder would have fell down, had not the thread supported it.

P. S. 2d. Notwithstanding the weight supported by the thread was constant, in all the inclinations of the cylinder tried in the above experiment, yet it is certain, that when the cylinder has become nearly horizontal, the weight on the thread begins at a certain point to decrease, and continues so to do as the cylinder sinks, till at length it floats on the water, and the thread sustains no part

part of its weight; some of the learned Correspondents to your *New Series of the Repository* will I hope give the investigation of these curious particulars.

J. F.

ARTICLE XVIII.

Demonstrations of Lawsons Propositions Proposed in

ARTICLE LII. VOL. II. P. 465.

PROP. XLVII. Fig. 603. Pl. 31.

Demonstrated by Meffrs. Campbell, Dawes, and Johnson.

By similar triangles,

$$\begin{aligned} AD(CB) : ED &:: BF : AB(DC), \text{ wherefore} \\ CB \cdot BF : ED \cdot DC &:: BF^* : DC^*, \text{ and componendo,} \\ CB \cdot BF + ED \cdot DC &:: ED \cdot DC :: AF^* : DC^*, \text{ But,} \\ AE : AF &:: DE : DC, \text{ consequently} \\ EA \cdot AF : ED \cdot DC &:: AF^* \cdot DC^*; \text{ therefore} \\ EA \cdot AF &= ED \cdot DC + CB \cdot BF. \quad Q. E. D. \end{aligned}$$

The same, by Meffrs. Lowry, Tyro Philomatheticus, Whalley, and Whitley.

Complete the rectangle BCEH, and draw BI perpendicular to AE. Then by similar triangles

$$\begin{aligned} AB(DC) : AI &:: AE : DE, \text{ and} \\ AE : EH(BC) &:: BF : FI; \text{ therefore,} \\ \text{rect. } CDE &= \text{rect. } EAI, \text{ and rect. } CBF = \text{rect. } AE \cdot FI; \text{ therefore} \\ CDE + CBF &= EAI + AE \times FI = EAF. \quad Q. E. D. \end{aligned}$$

PROP. XLVIII. Fig. 604, 605. Pl. 31.

Demonstrated by Meffrs. Campbell, Dawes, Tyro Philomatheticus, and Whalley. Fig. 604.

Let ABC be any right-angled triangle, and DEBF a rectangle inscribed therein. By similar triangles

$$\begin{aligned} DE(BF) : FC &:: AE : DF(EB), \text{ therefore} \\ BFC : FC^* &:: AEB : EB^*, \text{ and perm. et comp.} \\ AEB + BFC : AEB &:: DC^* : EB^*. \text{ But} \\ AD : DC &:: AE : DF, \text{ therefore,} \\ ADC : DC^* &:: AEB : EB^*, \text{ or, permutando,} \end{aligned}$$

ADC

ADC : AEB :: DC : EB; therefore
 $AD \cdot DC = AE \cdot EB + BF \cdot FC.$

Q. E. D.

The same, by Messrs. Johnson, Lowry, and Whitley. Fig. 605.

Let DBEF be a rectangle inscribed in the right angled triangle ABC, and draw FS perpendicular to AC. Then by similar triangles;

$AD : AE :: ES : EF (DB),$ and
 $AE : ED (BF) :: FC : CS;$ therefore

Rect. ADB = AES, and rect. BFC = AE · CS; wherefore
 $ADB + BFC = AES + AE \cdot CS = AEC.$

Q. E. D.

PROP. XLIX. Fig. 606, 607, 608. Pl. 31.

Demonstrated by Messrs. Campbell and Tyro Philomatheticus.
Fig. 606.

Let HF be drawn and produced to meet AB in D, and CT, CG being the two tangents, from the centre O draw OT, OG; join TG, and let TC meet FH in I.

Because the \angle s FTH, FGH are right ones, a circle will pass through the points G, F, T, H; and the \angle FTH will be equal to the \angle OTI; therefore the \angle ITH = OTB = OBT = AGT = FHT; consequently the \angle FIT = 2 \angle FHT, and therefore I is the centre of the circle GHTH. In like manner it may be shewn, that GC meets FH in the same point; C and I therefore coincide. Moreover, the \angle FHT = FGT = FBD, and the \angle DFB = TFH; consequently the \angle BDF = FTH, = a right angle.

Q. E. D.

The same, by Messrs. Dawes, Whalley, and Whitley. Fig. 607.

Three perpendiculars form the angular points of a \triangle upon the opposite sides, meet in the same point. In the \triangle ABH, AD and BE are perpendicular (Eu. 31, III.); therefore HG passing through F is perpendicular to AB. But it remains to be proved that C is in the line GH; draw EK perpendicular to AB, then the \triangle s AEK, AHG being similar, the \angle AEK = AHG, but the \angle IEA (CEH) = AEK (Eu. 32, III.); therefore the \angle CEH = CHE, and the \triangle CHE is isosceles; in the same manner the \triangle CHD is proved to be isosceles; and the \triangle s HEF, HDP being right angled at E and D, a circle will pass through the points D, F, E, H, whose centre is in the common hypotenuse HF, but CE = CH = CD; therefore C is the centre of the circle,

and is in the line HG ; consequently HC, CF produced will be perpendicular to AB.

Q. E. D.

The same, by Mr. John Lowry. Fig. 608.

Let G, D, be the points where the equal tangents touch the circle, and let the lines joining the points F, H meet the diameter in E ; then because GB is perpendicular to AH, and AD to BH, HEF will be perpendicular to AB, by a well known property of plane Δ s ; wherefore the truth of the proposition will appear manifest if we can prove that two equal tangents drawn from the points D, G meet each other in the line HF. Now if they do meet in HF it must be where the radius OQ, drawn perpendicular to GD, meets HF, otherwise they could not be equal.

Let OQ produced meet HF at C and join CD, CG ; then because of the right angles at D and E, the points D, B, E, F are in a circle, therefore the \angle DBG \equiv DEC, but the \angle DBG at the circumference on the whole arch DG, is \equiv to the \angle DOE at the centre, on half the arch DQ ; therefore the \angle DEC \equiv DOC, and the points O, E, D, C are in a circle ; wherefore the \angle ODC \equiv OEC \equiv a right angle, therefore CD is a tangent to the circle at D ; and in the same manner it may be shewn that CG is a tangent at G.

Since drawing up the above, I have been favoured with the following elegant demonstration of this property by my ingenious and worthy friend Mr. JOHN FLETCHER. I trust he will excuse the liberty I have taken in thus making it public.

To the centre O draw DO, GO and join GD, DB ; then since the angle GCD is the supplement of the angle GOD \equiv the sum of the angles AOG, BOD \equiv twice the sum of the angles ADG, BGD \equiv twice the angle AFG, it follows that the angle GCD is equal to the angle at the centre of a circle passing through G, D, F ; and as CG \equiv CD, C is the centre itself, and therefore CF \equiv CD ; but the angle DBA is \equiv CDA \equiv CFD \equiv AFE, and as A is common, AEF \equiv ADB \equiv a right angle. Q. E. D.

PROP. L. Fig. 609, Pl. 31.

*Demonstrated by Meffrs. Campbell, Dawes, Johnson, Lowry,
Tyro Philomatheticus, Whalley, and Whitley.*

Let BQ be the chord of 60° , equal to the radius, and join BF, FQ, and EF, then the angles BAF, BQF on the same arch are equal, and the triangles EAF, BFQ are isosceles ; therefore they are similar, and $AF : EF :: EF : FB$

Q. E. D.

PROP.

PROP. LI. Fig 610, Pl. 31.

*Demonstrated by Meffrs. Campbell, Dawes, Johnson, Lowry,
Tyro Philomatheticus, Whalley, and Whitley.*

Let the line AB be divided at C in extreme and mean proportion, that is, such that $AB : AC :: AC : CB$ then it is evident that $AB^2 : AB \times AC :: AB \times AC : AB \times CB$, which is the proportion mentioned in the proposition.

PROP. LII. Fig. 611, Pl. 31.

*Demonstrated by Meffrs. Campbell, Dawes, Johnson, Lowry,
Tyro Philomatheticus, Whalley, and Whitley.*

Let A, B, C , be the three lines. Then
 $A : B :: B : C$, or $A \times C = B^2$, $\therefore A \times (A + C) = A^2 + B^2$.
 Conseq. $A^2 + B^2 : A \times B :: A \times (A + C) : A \times B :: A + C : B$.
 Q. E. D.

PROP. LIII. Fig. 612, Pl. 31.

*Demonstrated by Meffrs. Campbell, Dawes, Johnson, Lowry,
Tyro Philomatheticus, Whalley, and Whitley.*

Let ABC be any right angled triangle, and CD perpendicular to the hypotenuse AB .

The triangles ACB, CDB , being equiangular,
 $AC : AB :: CD : CB$, or $2AC \times CB = 2AB \times CD$.
 Therefore $(AC + CB)^2 = AC^2 + BC^2 + 2AC \times CB$,
 $= AB^2 + 2AB \times CD$
 $= AB \times (AB + 2CD)$.
 Consequently $AB : AC + CB :: AC + CB : AB + 2CD$.
 Q. E. D.

PROP. LIV. Fig. 613, 614, 615, 616, 617, 618, Pl. 31.

Demonstrated by Mr. Colin Campbell, of Liverpool. Fig. 613.

In AD produced take $DG = AB$, draw GE to meet the circle in K , and join AK, AE, KF . Because
 $AB \cdot BG = BE^2$, $AFK = AEK =$ a right $\angle = BAF$ (hyp.),
 therefore EK is parallel and equal to AD ($= BG$);
 therefore FB and KG are parallel; wherefore $\angle ABF = AGE = AEB$, and therefore, seeing the Δ s AFB, ABE, BEG , are similar,

$AF : AB :: AB : BE :: BE : BG$ or AD . Q. E. D.

The

The same, by Mr. John Dawes, of Birmingham. Fig. 614.

Continue AF to AL, make $AL = BE$; unite FB and LD, which, by hypothesis, must be parallel; to prove this, describe the semi-circles AHD, AMB, join AH, AE, HD, MB. Then it will be

$AB : AH (BE) :: AH (AL) : AD$, therefore the Δ s ABE, LAD are similar, and $\angle DAP = DLA$, therefore the $\angle DPA$ is a right angle; draw HP, MR, and the $\angle HAP = HDP$ and MAR (HAP) = MBR; therefore HDP = MBR, and HD, MB are parallel, therefore LD and FB are parallel, and therefore $AF : AB :: BE (AL) : AD$. *Q. E. D.*

The same, by Mr. John Lowry. Fig. 615.

Produce EB to meet the circle again at S, and draw FI parallel to AB, meeting EB at I, then EI is evidently equal to BS, and by the property of the circle,

$AB : BS (BE - AF) :: BE : BD$; therefore
 $AB \times AD : AD \times (BE - AF) :: BE^2 : BD \times BE$;
 but $AB \times AD = BE^2$, by hypothesis, therefore
 $AD \times (BE - AF) = BD \times BE$, or
 $(AD - BD) \times BE = AB \times BE = AD \times AF$.

Wherefore $AF : AB :: BE : AD$. *Q. E. D.*

The same, by Tyro Philomatheticus, of Hull. Fig. 616.

Make $DC = AB$, on AC describe a semi-circle, then as BE is perpendicular to AC it will be a mean proportional between AB and BC, or AB and AD, and AF being perpendicular to AC, and FD drawn, it is manifest that FD is a diameter of the circle AFED; now the angles FED and AEC being each in a semi-circle, are right ones, and consequently equal; take away the common angle AED, and we shall have $\angle FEA = \angle DEC$, and (by Simpson's Geometry, PI. 15.) the $\angle FAE = \angle ECD$; whence the Δ s FEA and DEC are similar, therefore

$AF : CD = AB : AE : CE$, again, by sim. Δ s
 $AE : CE :: BE : BC = AD$; whence
 $AF : AB :: BE : AD$. *Q. E. D.*

The same, by Mr. James Whalley, of Bolton. Fig. 617.

On AD produced take $DC = AB$; then $AD = BC$; draw FP parallel to AD meeting BE in H, produce EB to meet the circle at G. Join AE, CE, and FB. Then

AB

$AB \times BD = EB \times BG = EB \times EH$, and

$AB : EB :: EH : BD$ (HP); but by constr.

$AB : EB :: EB : BC$, therefore

$EH : HP :: EB : BC$; wherefore CE passes through P , consequently $\angle BCE = HPE$, and arch $AC = FE$; hence $\angle AEB = FPE$, and $DC = AB$, $DP = AF$, therefore $FB = PC$, and the $\angle ABF = AEB$; the triangles ABF and ABE are therefore similar, consequently,

$FA : AB :: AB : BE :: BE : BC$ or AD .

Q. E. D.

The same, by Mr. John Whitley, of Attercliffe Academy.
Fig. 618.

Join DE and through F , draw EFG meeting DA produced in G . Then because the $\angle DAF$ is a right angle, the $\angle DEF$ will also be a right angle, therefore

$DB \times BG = BE^2$, but $AD \times AB = BE^2$, therefore

$AB \times AD = DB \times BG$; therefore

$AD : DB :: BG : AB$, and by division

$AB : DB :: AG : AB$; and by hypothesis

$AF : AB :: BE : AD$, also,

$AB : BE :: BE : AD$, therefore

$AF : AB :: AB : BE$, and.

$AF \times BE = AB^2$, therefore

$AG : AF :: BE : DB$; which is true, the triangles AGF , DBE , being evidently similar.

ARTICLE XIX.

Demonstrations of Lawson's Propositions proposed in

ARTICLE VI. VOL. III. P. 71.

PROP. LV. Fig. 619, Pl. 31.

Demonstrated by Meffrs. Campbell, Collins, Dawes, Johnson, Tyro Philomatheticus, Whalley, and Whitley.

Let ACB be a triangle right-angled at C , and CD perpendicular to the hypotenuse AB . Then

$AB : AC :: AC : AD$, and convertendo,

$AB : AB - AC :: AC : AC - AD$, and permutando

$AB : AC :: AB - AC : AC - AD$, wherefore

$AB - AC : AC - AD :: AC : AD$.

Q. E. D.

PROP.

PROP. LVI. Fig. 619, 620, 621, Pl. 31.

Demonstrated by Messrs. Campbell, Johnson, and Whalley.
Fig. 619.

Draw the radius OC; then by similar triangles,
 $KH : HC :: HC : HO$, therefore
 $KH \cdot HO = HC^2 = BH \cdot HD$; consequently
 $BH : DH :: BK : KD$ (Conv. Prop. I.), therefore
 $FH : HG :: FI : IG$ (Prop. II.); hence
 $FH \cdot HG = HC^2 :: FI : IG$. *Q. E. D.*

The same, by Messrs. Dawes and Whitley. Fig. 620.

Upon FG as a diameter describe the semi-circle GLF, join ρP , CF, CG; P , ρ being the centre of the circle and semi-circle; draw the tangent LH, which is equal to CH because their squares are each = to $GH \cdot HF$; and join LG, LF and LI; LI is perpendicular to GF. For the Δ s HKI and $H\rho P$ are similar; therefore $PH \cdot HK = \rho H \cdot HI$; but conceive CP, $L\rho$ to be joined then $PH \cdot HK = HC^2$ and therefore LI is perpendicular to FG. Now the Δ s HFC and HCG being similar, as also HFL and HLG.

$HF^2 : HC^2 :: FC^2 : GC^2$, and
 $HF^2 : HI^2 (HC^2) :: LI^2 : LG^2$. Therefore
 $FL^2 : LG^2 :: FC^2 : CG^2$; but
 $FL^2 : LG^2 :: FI : IG$; therefore
 $FC^2 : GC^2 :: FI : IG$; and therefore
 $FH^2 : HC^2 :: FI : IG$. *Q. E. D.*

The same, by Messrs. Tyro Philomatheticus and Collins.
Fig. 621.

From the centre O draw $OE \perp$ to FG and join OC, then by similar triangles,

$HO : HE :: HI : HK$ therefore
 $HE \cdot HI = HO \cdot HK = HC^2 = HG \cdot HF$; whence
 $HG : HE :: HI : HF$, or
 $2HG : 2HE = HG + HF :: HI = HF + FI : HF$, and
 $2HG - (HG + HF) = FI + IG : FI :: HF + FG : HF$;
 wherefore by division and conversion

$HF : HG :: FI : IG$, and therefore
 $HF^2 : HG \times HF = HC^2 :: FI : IG$. *Q. E. D.*

PROP. LVII. Fig. 622, 623, 624, 625, Pl. 31.

Demonstrated by Mr. Colin Campbell. Fig. 622.

Draw $BG \perp$ and $BF \parallel$ to AC , and O being the centre of the circumscribing circle, join OC .

The angle $BAC =$ to the angle ACB , therefore
 $ABC = CBG = OCB$ (because O is in BG), therefore
 $\angle OCB = ABC = ACB = CBE + CEB = \angle CEB$; conseq.
 $GCO = CEB = FBD$; also $FB = AG = OC$;

Therefore OC is equal to DB . *Q. E. D.*

The same, by Messrs. Collins, Dawes, Whalley, and Whitley. Fig. 623.

Draw the perpendiculars BI , CK , (which continue to H); their intersection, G , is the centre of the circle circumscribing the triangle, but $AC = CE$,

Therefore HC is parallel to DE , but $AI = IC$, therefore $HG = GC$, but $BG = GC$, therefore $BGHD$ is an equilateral parallelogram, and $BD = BG$. *Q. E. D.*

The same, by Mr. Johnson, Birmingham. Fig. 624.

To the centre of the circumscribing circle O , draw AO , BO , and DO .

Now the $\angle s CBE + ABC =$ a right angle,
therefore the $\angle s DBO + DAO =$ a right angles.

Hence, by Eu. 22d. III. a circle will pass through the points D , B , O , A , therefore in the triangles DBO , BAO ,
the $\angle BAO = ABO = BDO = DOB$.

But $AO = OB$, therefore $OB = DB$. *Q. E. D.*

COROL. The right line DO bisects the $\angle ADB$.

The same, by Tyro Philomatheticus. Fig. 625.

Describe a circle about the Δ and draw BF . Then

$\angle DFB = BCA = 60^\circ$, and $CEB + CBE = BCA$;
but CE being equal to CB , $\angle CBE = CEB = 30^\circ$,
therefore the complement of $CEB = ADE = 60^\circ$;

Whence $BD = BF$, and FAC being a right angle,
 $FBC =$ a rt. \angle , but $BAC = ABC$, $\therefore FAB = FBA$.

Conse-

Consequently $BF = FA$ = the side of a regular hexagon, which, it is well known is equal to the radius of the circumscribing circle.

Q. E. D.

PROP. LVIII. Fig. 626, Pl. 31.

Demonstrated by Meffrs. Campbell, Collins, Dawes, Johnson, Tyro Philomatheticus, Whalley, and Whitley.

Join CE. Because $\angle ADB = CEB$, the triangles ABD, CBE are similar, therefore

$$BE : BD :: CB : AB; \text{ but}$$

$$DC : AD :: CB : AB, (\text{Euc. VI. 3.}); \text{ consequently}$$

$$BE : BD :: DC : AD.$$

Q. E. D.

PROP. LIX. Fig. 627, Pl. 31.

Demonstrated by Meffrs. Campbell, Collins, Dawes, Johnson, Tyro Philomatheticus, Whalley, and Whitley.

Because $BA : BD :: BD : BE$, and $BC : BD :: BD : BE$,
the Δ s ABD, DBE; and CBD, DBE, are similar;
whence $\angle AED = \angle ADB$, and $\angle DEC = \angle CDB$;
and therefore by similar triangles

$$AB : AD :: AD : AE, \text{ and } CB : CD :: CD : CE.$$

Therefore $BAE = AD^*$ and $BCE = CD^*$. Q. E. D.

PROP. LX. Fig. 628, Pl. 31.

Demonstrated by Meffrs. Campbell, Collins, Dawes, Johnson, Tyro Philomatheticus, Whalley, and Whitley.

Because the vertical \angle of the triangle ABC, inscribed in the semi-circle ABC is a right angle, the triangles AFE, EGC are similar to ABC, and consequently to one another.

Therefore $AE : EF :: GE : EC$,
therefore $GE \cdot EF = AE \cdot EC = EH^*$.

Consequently $EG : EH :: EH : EF$. Q. E. D.

From the preceding demonstration it appears that the triangle need not have been restricted to an isosceles one.

ARTICLE XX.

*Answers to the Mathematical Questions proposed in
ARTICLE V. No. XII.*

I. QUESTION 271, *answered by Yanto.*

The owners stock at the beginning of any year may be easily found by means of a table of the different orders of the figurate numbers. Thus at the beginning of

the 1st year his stock will be	1
2d.....	1
3d.....	1
4th.....	1 + 1
5th.....	1 + 2
6th.....	1 + 3
7th.....	1 + 4 + 1
8th.....	1 + 5 + 3
9th.....	1 + 6 + 6
10th.....	1 + 7 + 10 + 1
11th.....	1 + 8 + 15 + 4
&c.....	&c. &c. &c.

Hence it appears that the owners stock at the beginning of the 31st year will be equal to the sum of

the 31st term of the series 1. 1. 1 &c. =	1
28th..... 1. 2. 3 &c. =	28
25th..... 1. 3. 6 &c. =	325
22d..... 1. 4. 10 &c. =	2024
19th..... 1. 5. 15 &c. =	7315
16th..... 1. 6. 21 &c. =	15504
13th..... 1. 7. 28 &c. =	18564
10th..... 1. 8. 36 &c. =	11440
7th..... 1. 9. 45 &c. =	3003
4th..... 1. 10. 55 &c. =	220
1st..... 1. 11. 66 &c. =	1

That is, the owners whole stock is = 58425

In like manner all questions of this nature may be very readily answered.

Suppose

Suppose the number of years, to be 20, instead of 30. Then it is evident that the owners whole stock will be equal to the sum of

the 21st term of the series 1. 1. 1 &c

18th..... 1. 2. 3 &c

15th..... 1. 3. 6 &c

12th..... 1. 4. 10 &c

9th..... 1. 5. 15 &c

6th..... 1. 6. 21 &c

3rd..... 1. 7. 28 &c.

The sum in this case will be 1278.

Again, suppose the number of years to be 40 instead of 30, and that the calves begin to breed at the end of every two years.

In this case the owners whole stock at the beginning of the 41st year will be equal to the sum of

the 41st term of the series 1. 1. 1 &c

39th..... 1. 2. 3 &c

37th..... 1. 3. 6 &c

35th..... 1. 4. 10 &c

&c. &c.

The flock in this case is found to be 165580141.

The same, answered by Mr. James Campbell, at Mr. Flower's Academy, Islington.

By considering the nature of this question. I observe that the number of cows that calved at the end of these years will be as follows, viz.

3. 4. 5. 6. 7. 8. 9. 10. 11. 12

1. 1. 1. 2. 3. 4. 6. 9. 13. 19

and so on to 27. 28. 29. 30 years.

5896. 8641. 12664. and 18560, respectively, which are found by adding the last to the last but two.

Let s = the whole sum, and w, x, y , and z the four last terms of the series; then

$1+1+1+2+3+4+6+9+13\dots+w+x+y+z=s$, and

$1+1+1+2+3+\&c\dots+w=s-x-y-z$.

Take the latter of these from the former, and we have

$1+1+1+1+2+3+4+6+\&c\dots+x=s-x+y+z$;

add z to both sides of this equation and we get

$1+1+1+1+2+3+4+6+\&c\dots+x+z=s-x+y+2z$,

which is evidently the owners whole stock of cows and calves at the end of any number of years, and in the present case is equal to $8641+12664+2\times18560=58425$. *W. W. R.*

The same, by Mr. William Francis, Taplow Academy.

Let the lines in fig. 629, pl. 31. represent the years to the 10th, and the dots thereon the calves produced in their respective years. It will then appear, that the produce of calves, in any year, added to the last year but one, will give the number that will be produced the following year. Hence the number produced at the commencement of each year will be as follows, viz.

1st 2d 3d 4th 5th 6th 7th 8th 9th 10th 11th 12th
 1. 0. 0. 1. 1. 1. 2. 3. 4. 6. 9. 13.
 13th 14th 29th 30th 31st
 19. 28 and so on to 8641. 12664 18560. The sum of
 which is 58425 the number required.

Solutions to this question were also received from Messrs. Boole and Collins.

II. QUESTION 272, answered by Mr. Francis.

Let ABCD (fig. 630, pl. 31.) represent a section of the tub through its axis, the line gB the transverse diameter of the elliptical surface of the water when standing upon the inclined plane.

Draw BE perpendicular and gh parallel to CD, intersecting each other in n . Put $CD = a$, $AB = b$, $BE = h$, and $gh = x$.

Then $ED = \frac{1}{2}(a - b)$, $nh = \frac{1}{2}(x - b)$, and $gn = \frac{1}{2}(x + b)$; and by reason of the parallels ED , nh ,

$$ED : EB :: nh : nB = \frac{ED \cdot nh}{ED} = \frac{h(x - b)}{a - b}.$$

And by corol. 2d Prob. 26th Sect. 1st of Hutton's Mensuration.

$$\frac{gh\sqrt{(gh \cdot AB) - AB^2}}{gh - AB} \times 2618 Bn \times AB, \text{ or}$$

$(x\sqrt{[bx]} - b^2) \times \frac{2618 hb}{a - b}$ will express the content of the

ungula gAB , which put $= c$, the cubic inches $\frac{2}{3}$ ale gallons;

$$\text{Whence } x\sqrt{[bx]} = \frac{c(a - b)}{2618 hb} + b^2, \text{ and } x = 21.4115889.$$

And by the principles of trigonometry,

$$\frac{Fn}{gn} = \frac{2h(x - b)}{(a - b) \times (x + b)} = .170434, \text{ nat. tang. of } \angle Bgh,$$

the

the inclination of the plane upon which the tub stands. From whence, by help of the best tables, the $\angle Bgh$ is found to be $9^{\circ} 40' \frac{1}{2}$ nearly.

And thus the question was answered by Messrs. Cunliffe, Marrat, Thornoby, and Whitley.

III. QUESTION 273, answered by the Proposer.

To avoid complex Fractions, put $12x$ = the diameter of the cone's base, 12 being divisible both by 3 and 4; then, by the rules of mensuration

$$144x^6 \times \frac{3.141593}{4} \times \frac{\text{alt.}}{3} = 2412.743424, \text{ the solidity;}$$

whence we find the altitude $= \frac{64}{x^6}$, and consequently the slant height $= \sqrt{36x^6 + \frac{4096}{x^4}}$; this multiplied into $6x \times 3.141593$ half the circumference of the base gives the curve surface, that is

$$18.849558x\sqrt{36x^6 + \frac{4096}{x^4}} = 753.98232. \text{ Which equation reduced gives } x = 2: \text{ wherefore the diameter of the base is } 24, \text{ the altitude } 16, \text{ and the slant height } 20.$$

Now with respect to a conic *ungula* formed by a vertical plane; it was first shewn by Father Guido Grandi, an Italian Geometricalian, and has been well demonstrated by Mr. Emerson in the *Ladies' Diary* for 1738*, that the segment of the base formed by the vertical plane is to the curve surface of the *ungula*, as the radius of the base, to the slant height of the cone. Find therefore, the versed sine of that segment of the base which contains $\frac{1}{2}$ of it; thus, from a table of circular segments the versed sine of a segment containing $\frac{1}{2}$ of the area of a circle to the diameter 1 is .254069; therefore

$$\text{As } 1 : 24 :: .254069 : 6.097656 = \text{AS (fig. 681, pl. 31.)}.$$

$$\text{Then } AP - \text{AS} = 12 - 6.097656 = 5.902344 = \text{PS};$$

* An ingenious investigation of a similar theorem was given by Mr. Cunliffe in No. XIII. *Repository*, page 109. See also Dr Hutton's translation of Montucla's Ozanam, Vol. I. page 416.

and

and lastly, as is manifest from the consideration of Mr. Emerson's Theorem, and the nature of similar triangles,

As $AP(12) : AB(20) :: SP(5.9023 \&c.) : 9.83724 = VB$, the distance required from the vertex of the cone.

Neat solutions to this question were also received from Messrs. Cunliffe, Francis, Thornoby, and Whitley.

IV. QUESTION 274, answered by Mr. Thomas Bazley.

The weight p suspended on the wheel $BFDC$ (fig. 632, pl. 31.) elevates the weight q suspended on the axle AEC ; it is required to determine the pressure on the axis C .

Through the centre C and the points of contact A and B , draw $DACB$. Put $CA = a$, $CB = b$; then it is plain by the property of the lever, that $\frac{qa}{b}$ is the weight which hung at B would balance q at A ; and therefore $p - \frac{qa}{b} = \frac{pb - qa}{b}$ is the motive force acting at B^* . Now the mass moved reduced to the distance CD or CB is (Sect. 6. Prop. I. Atwood on Motion) $\frac{qa^2 + pb^2}{b^2}$;

whence the accelerative force is

$$\frac{pb - qa}{b} \div \frac{qa^2 + pb^2}{b^2} = \frac{b(pb - qa)}{qa^2 + pb^2}.$$

Again, the weight q reduced to the distance $CD = CB$, by the Prop. above quoted, is $\frac{qa^2}{b^2}$, and consequently

$\frac{qa^2}{b^2} + \frac{qa}{b}$ is the mass causing the tension of the string AB (Sect.

10.

* The ensuing part of the solution will appear more perspicuous, by conceiving (as in fig. 633, pl. 31.) the weight q to be dispersed (uniformly) in the periphery of the circle AEC , and the weight $\frac{qa}{b}$ dispersed in the periphery of the circle $BFDC$; and

the weight $W = p - \frac{qa}{b}$ as giving motion to this system.

10. Prop. 1. Ibid.) ; and therefore that tension is

$$\left(\frac{qa^*}{b^*} + \frac{qa}{b} \right) \times \frac{b(pb - qa)}{qa^* + pb^*}$$

that is, the mass into the accelerating force. Lastly, add to this, the weight of the system, viz. $q + \frac{qa}{b}$, and we have the whole pressure on the axis

$$= \left(q + \frac{qa}{b} \right) + \left(\frac{qa^*}{b^*} + \frac{qa}{b} \right) \times \frac{b(pb - qa)}{qa^* + pb^*},$$

which is easily reduced to $\frac{pq(a + b)^*}{qa^* + pb^*}$.

COROL. If $b = a$, as is the case in the pulley we have

$$\frac{pq \times (2a)^*}{(q + b)a^*} = \frac{4pq}{p + q} \text{ for the pressure on the axis.}$$

Hence whatever be the radius of the pulley, the pressure on the axis is the same.

Mr. Jeffreys, Marrat and Thornoboy also sent solutions to this question.

V. QUESTION 275, answered by Mr. Cunliffe.

Fig. 634. Pl. 31. From the centre O upon DM let fall the perpendicular On, and join OF. Put $AB = BD = ea$, $BM = x$, and $MF = MP = y$, then $MO = x - a$ and by Euc. I. 47. $DM = \sqrt{(4a^* + x^*)}$: and by reason of the similar Δ s MDB , MO_n ,

$$Mn = \frac{x(x - a)}{\sqrt{(4a^* + x^*)}} \text{ and } On = \frac{2a(x - a)}{\sqrt{(4a^* + x^*)}}.$$

$$\text{Again } nF^* = OF^* - On^* = \frac{a^* \times (8ax - 3x^*)}{4a^* + x^*};$$

$$\text{Whence } nF = a \sqrt{\frac{8ax - 3x^*}{4a^* + x^*}}, \text{ and therefore}$$

$$MF = MP = Mn + nF, \text{ that is,}$$

$y = \frac{x(x - a)}{\sqrt{(4a^* + x^*)}} + a \sqrt{\frac{8ax - 3x^*}{4a^* + x^*}}$, is an equation expressing the nature of the curve which is the locus of the point P. Moreover

$$xy = \frac{xr(x - a)}{\sqrt{(4a^* + x^*)}} + ax \sqrt{\frac{8ax - 3x^*}{4a^* + x^*}} \text{ is the fluxion of the}$$

the area. The correct fluent of the first member is

$$\frac{x}{2} \sqrt{(4a^2 + x^2)} - a \sqrt{(4a^2 + x^2)} + 2a^2 - 2a^2 \times \text{h.l.} \left(\frac{x + \sqrt{(4a^2 + x^2)}}{2a} \right).$$

But the fluent of $ax \sqrt{\frac{8ax - 3x^2}{4a^2 + x^2}}$ is not to be expressed by any method which I am acquainted with, without infinite series; it may be integrated by means of a series as follows. Assume

$$\sqrt{\left(\frac{8ax - 3x^2}{4a^2 + x^2} \right)} = Ax^{\frac{1}{2}} + Bx^{\frac{3}{2}} + Cx^{\frac{5}{2}} + Dx^{\frac{7}{2}} + \text{etc.}$$

By squaring the equation, and expanding $\frac{8ax - 3x^2}{4a^2 + x^2}$ by division; and then by equating the homologous terms on each side of the equation, we shall obtain

$$\sqrt{\left(\frac{8ax - 3x^2}{4a^2 + x^2} \right)} = \frac{\sqrt{(2a)}}{2a} \times : \left(2x^{\frac{1}{2}} - \frac{3x^{\frac{3}{2}}}{8a} - \frac{73x^{\frac{5}{2}}}{256a^2} + \frac{165x^{\frac{7}{2}}}{4096a^3} + \frac{18085x^{\frac{9}{2}}}{262144a^4} \text{ etc.} \right)$$

$$\text{Therefore the fluent of } ax \sqrt{\left(\frac{8ax - 3x^2}{4a^2 + x^2} \right)} =$$

$$\sqrt{(2ax)} \times : \left(\frac{2x}{3} - \frac{3x^2}{40a} - \frac{73x^3}{1792a^2} + \frac{165x^4}{36864a^3} + \frac{18035x^5}{2883584a^4} \text{ etc.} \right)$$

Wherefore the correct expression for the space DMP, is

$$\frac{x}{2} \sqrt{(4a^2 + x^2)} - a \sqrt{(4a^2 + x^2)} + 2a^2 - 2a \times \text{h.l.} \left(\frac{x + \sqrt{(4a^2 + x^2)}}{2a} \right)$$

$$+ \sqrt{2ax} \times : \left(\frac{2x}{3} - \frac{3x^2}{40a} - \frac{73x^3}{1792a^2} + \frac{165x^4}{36864a^3} + \text{etc.} \right)$$

This Question was ingeniously answered by Messrs. Marrat and Whitley.

VI. QUESTION 276, answered by Mr. George Roy.

Since the pendulum composed of the ball of copper, and a slender rod of given length l in inches, and given weight w ounces, made v vibrations in s seconds, it will be easy to find the distance from the point of suspension to the centre of oscillation of the compound pendulum. For $\frac{v}{s}$ will express the number of vibrations

tions in 1 second ; and its reciprocal $\frac{s}{v}$ = the time of one vibration.

And as the distances from the points of suspension to the centres of oscillation of pendulums, are as the squares of the times of vibration,

we have $1^2 : \frac{s^2}{v^2} :: 89\frac{1}{3} : \frac{89\frac{1}{3} s^2}{v^2} = PV$ in fig. 635. pl. 31.

V being the centre of oscillation of the compound body. Here v and s being given, PV becomes known, and may, therefore, be denoted by L. Now in the figure, PB being = l, if C be the centre of gravity of the rod, and O its centre of oscillation, then will PC = $\frac{1}{3} l$ and PO = $\frac{2}{3} l$. Call BI the radius of the ball, x ; then, conceiving it suspended at B, and F its centre of oscillation, we shall have IF = $\frac{2}{3} x$. And if c = weight in ounces of a cubic inch of copper, and $n = 5236 \times 8$; $c n x^3$, will represent the weight of the ball. Now M denoting the mass of the cylinder, and M' that of the sphere, we have, by the nature of the centre of oscillation,

$$PV = \frac{(PO \times PC \times M) + (PF \times PI \times M')}{(PC \times M) + (PI \times M')}.$$

Let the respective lines and masses in this expression be denoted as above, and it will become

$$L = \frac{(\frac{1}{3} l \times \frac{2}{3} l \times w) + (l + x) \times (l + \frac{2}{3} x) \times c n x^3}{\frac{1}{3} l w + (l + x) c n x^3}$$

This, after a little reduction, becomes

$$\left\{ \frac{2}{3} c n x^3 + \frac{4}{3} c l n \right\} x^4 + \left\{ \frac{l^2 c n}{L l c n} \right\} x^3 = \frac{1}{3} L l w - \frac{1}{3} l^2 w$$

an equation which it is not necessary to throw into any other form, until some values of L, l, w, &c. are specified ; when x may readily be found, and consequently $c n x^3$ the weight of the copper ball.

VII. QUESTION 277, *answered by Mr. Cunliffe.*

Let AB (fig. 636, pl. 31.) represent the cylinder just immersed in the fluid, with its axis perpendicular to the surface. By the principles of hydrostatics the pressure of the fluid upon any part Ea of the surface of the cylinder is equal to the weight of a column of the fluid, whose base is equal to the surface of the part, and height equal to $\frac{1}{2}(Ba)$.

That

That is, the pressure upon the surface of the part Ba , is proportional to the solid content of a prism, whose base is equal to the surface of the part Pa , and height $\frac{1}{2}(Ba)$: But the surface of the part Ba is as the height Ba , therefore the pressure upon the surface of the part Ba is as $(Ba)^2$, or as the square of the height Ba . And consequently the pressure upon the surface of the part Aa , will be as $(BA)^2 - (Ba)^2$. And as the pressures upon these two parts are to be equal by the question, we shall have

$$(BA)^2 - (Ba)^2 = (Ba)^2, \text{ or } (BA)^2 = 2(Ba)^2;$$

wherefore if Ba be taken upon BA equal to the side of a square whose diagonal is BA , a will be the point where the cylinder is to be cut, so that the pressures upon the surfaces of the parts Ba and aA shall be equal to each other.

Et cætris paribus, if it was required to cut the cylinder, so that the pressures upon the surfaces of the two parts might have the given ratio of m to n ; that is, that the pressure upon the convex surface of the upper part (Ba) may be to the pressure upon the convex surface of the lower part (aA) as m to n . Then from what has been deduced

$$(Ba)^2 : (BA)^2 - (Ba)^2 :: m : n, \text{ whence}$$

$$(Ba)^2 = \frac{m(BA)^2}{m+n} \text{ which will determine the point } a \text{ where the cylinder is to be cut in this case.}$$

The same, answered by Mr. William Marrat, of Boston.

Put BA the length of the cylinder $= l$, and let the distance of the section from the surface of the water, or $BA = x$; then, because the pressure at A is as $AB = AC$, the pressure at any point a will be as Ba or ab ; therefore the pressure on the part Ba will be as the area of the ΔabB , and that against aA as the area $CbaA$; that is, $\frac{1}{2}x^2 = \frac{l+x}{2} \times (l-x) = \frac{1}{2}(l^2 - x^2)$, by the question.

$$\text{Therefore } x = l\sqrt{\left(\frac{1}{2}\right)}.$$

This question was likewise ingeniously answered by Messrs. Francis, Thornoby, and Whitley.

VIII. QUESTION 278, answered by Ambulator.

After the body had passed over the plane AB , (fig. 670. pl. 32.) if there were no loss of velocity at the angle B , the time of running over the space $BD = 2AB$ with the acquired velocity, would be equal

equal to the time employed in passing down AB; and, in this case, since the times of running down planes of equal altitudes are as their lengths, the problem would be solved by simply setting off from A to BD, $AE = 2AB$.—But, the whole velocity at B : the velocity along BD :: AB : BC :: $aB : Bc :: \text{rad.} : \text{cos. } B$. Hence, since the times are inversely as the velocities, if T be the time of running over BD with the whole velocity acquired in falling down AB, we have $\text{cos. } B : \text{rad.} :: T : \frac{T}{\text{cos. } B}$ time of running over BD with the reduced velocity. Or, if AB represent the time down AB, we have $\text{cos. } B : \text{rad.} :: AB : \frac{AB}{\text{cos. } B} :: AB : \frac{AB}{BC}$,

for the time along BD. Hence take $AE = AB + \frac{AB}{\text{cos. } B}$
 $= AB + \frac{AB}{CB}$, and set from A to BD, and AE is the length and position of the required plane.

It was also answered by Mr. Marrat.

IX. QUESTION 279, *answered by Mr. Cunliffe.*

Let QCP (fig. 638. pl. 31.) be the given circle, O its centre; and imagine the bodies A and B to move at the same time from the point P, the body A along the periphery, and the body B along the given chord PQ, in such a manner that the straight line AB connecting them may always pass through the centre O of the circle. It is very obvious that the curve which is the locus of the centre of gravity of the two equal bodies A and B, or which is the same thing the middle point in the straight line connecting them will pass through the points P and Q. Draw the radius OC perpendicular to PQ, and cutting it in m , and let QGP represent the curve which is the locus of the centre of gravity of the two bodies; and let V be the point where this curve cuts the radius OC, and draw GH perpendicular to OC. Put $CV = Vm = c$, $Om = b$, $VH = x$, and $HG = y$.

Then $mH = c - x$, and $OH = b + c - x$; And by Euc. I. 47. $OG = \sqrt{(OH^2 + HG^2)} = \sqrt{(b+c-x)^2 + y^2}$

And by reason of the parallels mB , HG ;

$OH : mH :: OG : BG = GA$, and by composition

$OH : Om + mH :: OG : OG + GA = OA = OC$,

VOL. III.

R

whence

whence $(Ox + 2mH) \times OG = OH \times OC$,
which being expressed algebraically is

$$\{b+2(c-x)\} \times \sqrt{\{(b+c-x)^2 + y^2\}} = (b+c-x) \times (b+2c), \text{ or}$$

$$\sqrt{\{(b+c-x)^2 + y^2\}} = \frac{(b+c-x) \times (b+2c)}{b+2(c-x)}, \text{ which}$$

is therefore the equation of the curve which is the locus of the centre of gravity of the two bodies.

When $2(c-x) = -b$, that is $2(x-c) = b$, or $x = c + \frac{1}{2}b$, it is plain that y will be infinite. Hence, it appears that the curve has two infinite legs; and the asymptote is parallel to the given chord QP , and bisects On .

X. QUESTION 280, answered by Mr. Cunliffe.

Let DIB (fig. 639, pl. 31.) be half the harmonical curve, CD its axis, and CB its greatest ordinate. Suppose the rectangle $HIKC$ to be the greatest that can be inscribed in the curve; and with the radius CD and centre C describe a circle cutting the ordinate HI in F , and CB in Q . Put $DC = r$, $DH = x$, $HI = y$, the arc $DF = z$, and $c = 3.1416$, half the circumference of a circle

whose radius is 1. Then by the property of the curve $y = \frac{az}{r}$,

where a is a constant quantity easily determined from the data.

Whence $HI \times CH = \frac{az}{r} \times (r-x)$ will express the area of the

rectangle CI , which is to be a maximum by the question; therefore $z \times (r-x)$ must be a maximum; putting its fluxion = 0,

$rz - zx - xz = 0$, whence $zx = (r-x) \times z$; but it is well known that $z = \frac{rx}{\sqrt{(2rx-x^2)}}$, by means of which, exterminating z out of the preceding equation, and it will become

$$zx = \frac{rx(r-x)}{\sqrt{(2rx-x^2)}}; \text{ whence } z = \frac{r(r-x)}{\sqrt{(2rx-x^2)}};$$

or the arc $DF = \frac{CD \times CH}{HF}$. Now $\frac{CD \times CH}{HF}$ is known to

express the tangent of the arc QF , or the cotangent of the arc DF . Wherefore the question is now to find such an arc of a circle as shall be equal to its cotangent. An arc of a circle equal to its cotangent,

tangent, from a few approximations by the method of trial and error will be found to be $49^{\circ} 17' \frac{3}{5}$ very near. The cosine of $49^{\circ} 17' \frac{3}{5}$ to rad. 1 is .652092, and therefore $CH = .652092 \times r = 1.804184$. Also, by the property of the curve and the question $CB = (a \div r) \times$ quadrant $DQ = \frac{1}{4}a \times 3.1416 = a \times 1.5708 = 10$; whence $a = 10 \div 1.5708$. Moreover, the length of the arc

$$DF = 1.7206659; \text{ whence } HI = (a \div r) \times DF = \frac{5}{1.5708}$$

$\times 1.7206659 = 5.477037$, and $2HI = 10.954074$ will be the whole length of the greatest rectangle that can be inscribed in the harmonical curve whose base is 20, and height 2, and from what has been before deduced $CH = 1.304184$ the height of the rectangle; Hence the area is found to be 14.286128.

The same, by Mr. John Whitley, Attercliffe.

Let MHQGN (fig. 64b, pl. 91.) represent the harmonic curve, and suppose that CHGD is the required rectangle. Put $OI = OF = a = 6.96618$, $OQ = Om = b = 2$, and $x = OP$. Then by the property of the circle $IF = \sqrt{(a-x) \times 2a}$, $EF = 2\sqrt{(a^2 - x^2)}$, and the length of the arc

$$EIF = \frac{8\sqrt{(a-x) \times 2a}}{3} - 2\sqrt{(a^2 - x^2)} = \text{by the}$$

property of the curve, to GH. And by sim. Δ s,

$$OF : OP :: Om : On = \frac{bx}{a}; \text{ therefore}$$

$$GH \times CH = \frac{8\sqrt{(a-x) \times 2a}}{3} - 2\sqrt{(a^2 - x^2)} \times \frac{bx}{a} = a$$

max. per question; the fluxion of which being made = 0, and reduced gives

$$(4a - 6x) \sqrt{(a-x) \times 2a} = a^2 - 2x^2; \text{ from this equation } x \text{ is found} = 4.1589 \text{ nearly, and the area of the rectangle} = 14.268.$$

Mr. George Roy and Mr. Thornoby answered it.

XI. QUESTION 281, answered by the Proposer, Mr. Dawes.

In fig. 641, pl. 31. let ASL represent the required spherical triangle, make the $\angle \text{CSL} =$ half the given $\angle \text{ASL}$, continue SL to G so that $\text{SG} = 91^\circ 39' =$ half the given sum. Draw the great circle GC perpendicular to SG and let it meet SC in C ; CL making the $\angle \text{CLG} =$ half the complement of the given $\angle \text{ALS}$.

By Trigonometry

As $\text{tang. GLC} : \text{tang. GSC} :: \text{fin. GS} : \text{fin. GL} = 51^\circ 41' 29''$.
Hence $\text{LS} = 89^\circ 57' 31''$, therefore $\text{AS} = 80^\circ 1' 26''$,
and $\text{LA} = 63^\circ 19' 8''$, which were required.

XII. QUESTION 282, answered by Cap. Geo. Gorry.

It has often been shewn that a whole number, having no integral root, has no terminating decimal root, and it is generally admitted, as stated in the question, that the decimal obtained by extracting any root of a whole number cannot be a repetend; but I know of no investigation of this matter which is so perspicuous, and at the same time so concise, as the one given in Vol. II. of Mr. Manning's Introduction to Arithmetic and Algebra. It may be found at page 84, of that ingenious performance, and is as follows:

"If possible, let N be a number the figures of whose m th root circulate; and let $\frac{S}{R}$ be equal to the value of the previous figures, and the value of the circulating part. I say in that case

$$\sqrt[m]{\text{N}} = \frac{S}{R}, \text{ or } \text{N} = \frac{S^m}{R^m}.$$

For, if N be not equal to $\frac{S^m}{R^m}$, let

$$\text{N} = \frac{S^m}{R^m} \pm d = \frac{S^m \pm dR^m}{R^m}; \text{ then } \sqrt[m]{\text{N}} = \frac{\sqrt[m]{(S^m \pm dR^m)}}{R};$$

That is, the figures obtained for $\sqrt[m]{\text{N}}$ agree throughout with the decimal fraction obtained by dividing the figures of $\sqrt[m]{(S^m \pm dR^m)}$ by R ; but the figures of $\sqrt[m]{\text{N}}$ by hypothesis agree with those obtained by

by dividing S by R , therefore the figures of $\sqrt{S^m \pm dR^m}$ are the figures of S , or $\sqrt{S^m \pm dR^m} = S$, which is absurd; therefore in that case \sqrt{N} would be equal to $\frac{S}{R}$; but because, by hypothesis, N has no integral root, neither has it any fractional root; Therefore, the decimal, obtained by the operation of extracting the root of a whole number cannot circulate."

Mr. Cunliffe sent an answer to this question, and so did Mr. Whitley.

XIII. QUESTION 283, answered by Mr. Murrat.

ANALYSIS. (Fig. 642, pl. 31.) Let ABC represent the triangle with a circle inscribed, L being the point of contact thereof with the base AB . Through the centre O draw CO to meet the base in I , also draw CK perpendicular to AB , and let E be the middle of AB . By the question LK is given, and EL is known to be equal to half the difference of the sides AC , BC , which is given by the question. Also by Prop. IV. of Harrison's Propositions in Vol. 1st of the Repository $EI \times EK = EL^2$, whence EI becomes known, that is, the point I is given. Hence the following construction.

In the same right line take $EL = \frac{1}{2}$ the given diff. of the sides, and $LK =$ the diff. of the segs. of the base made by the point of contact of the inscribed circle, and that of those made by the perpend. and draw KC perpend. to EK . Now the point I being determined by the Analysis, from I to KC , apply $IC =$ to the given line bisecting the vertical angle. Draw LO perpend. to EK meeting IC in O ; then with the centre O and radius OL describe a circle, and from the point C draw two right lines to touch the circle and meet EK in A and B , and ABC is the triangle required, as is evident from the Analysis.

Messrs. Cunliffe, Dawes, and Swale answered it.

XIV. QUESTION 284, answered by Quinibus Flestrin.

Let CAB (fig. 643, pl. 31.) represent a rectangular quadrant of a given ellipsis, E the point of contact of the inscribed circle with the curve, join CE , and draw ED and EF at right angles to

CA and CB respectively. Also draw GH to touch the curve in E, and meet CA, CB, in G and H respectively. Put CA = a , CB = c , CD = EF = x , and DE = CF = y .

By Euc. I. 47. $CE^2 = CD^2 + DE^2 = x^2 + y^2$, and by the known property of the ellipsis $c^2 \times (a^2 - x^2) = a^2 y^2$.

Also $CD \times CG = CA^2$, or $CD = CA^2 \div CG = a^2 \div x$; and $CF \times CH = CB^2$, or $CH = CB^2 \div CF = c^2 \div y$.

Moreover in the right angled triangle GCH, E is the point of contact of the inscribed circle with the hypotenuse GH, therefore by a well known property of the rectangle

$$GE \times EH = (CG \times CH) = a^2 c^2 \div 2xy.$$

And by Lawlins Theorems, Prop. 36, and what has been deduced above

$CD \times CG + CF \times CH = CE^2 + GE \times EH = CA^2 + CE^2$, that is $x^2 + y^2 + a^2 c^2 \div 2xy = a^2 + c^2$; from this equation and from the property of the ellipse quoted above, x and y may be determined, and by means of these the radius SE easily found.

The same, by Mr. Passman, the Proposer.

Fig. 644, pl. 31. BNKD is the given quadrant of the ellipsis. Let NST represent the greatest inscribed circle, touching the ellipsis in N. Draw NC and OT perpend. to BD; and NM and OS perpend. to LD. AL is a tangent to the ellipsis and circle at the point N. Let $a = BD$, $c = DK$, $x = DC$.

Then, by Emerson's Conic Sections $\frac{a^2}{x} = AD$,

and, by the same $CN = \frac{a}{c} \sqrt{(a^2 - x^2)}$.

Moreover $AC = \frac{a^2}{x} - x = \frac{a^2 - x^2}{x}$, and by Eu. I. 47.

$NA = TA = \sqrt{\left\{ \left(\frac{a^2 - x^2}{x}\right)^2 + \frac{c^2}{a^2} \times (a^2 - x^2) \right\}}$; conseq.

$DT = \frac{a^2}{x} - \sqrt{\left\{ \left(\frac{a^2 - x^2}{x}\right)^2 + \frac{c^2}{a^2} \times (a^2 - x^2) \right\}}$, the radius of the inscribed circle. By sim. Δ s,

$AC : AN :: CD (NM) : NL (LS) = x^2 \sqrt{\left(\frac{1}{x^2} + \frac{c^2}{a^2 - a^2 x^2}\right)}$.

And

And as $AC : CN :: AD : DL = \frac{ac}{\sqrt{(a^2 - x^2)}}$.

Hence $DS = \frac{ac}{\sqrt{(a^2 - x^2)}} = x \sqrt{\left(\frac{1}{x^2} + \frac{c^2}{a^2 - a^2 x^2}\right)}$.

But DS is equal to DT , that is,

$$\frac{a^2}{x} - \left(\frac{a^2 - x^2}{x}\right)^2 + \frac{c^2}{a^2} \times (a^2 - x^2) = \sqrt{(a^2 - x^2)} - x \sqrt{\left(\frac{1}{x^2} + \frac{c^2}{a^2 - a^2 x^2}\right)}. \text{ Or,}$$

$$\frac{a^2}{x} \sqrt{(a^2 - x^2)} + (2x^2 - a^2) \sqrt{\left(\frac{a^2 - x^2}{x^2} + \frac{c^2}{a^2}\right)} = ac.$$

From this equation x may be found.

The same, by Mr. W. Wallace, of the R. M. College.

ANALYSIS. Let abc (fig. 650, pl. 32.) be the given elliptic quadrant. Suppose the problem resolved, and that the inscribed circle touches the ellipse at d and the axes at e and f . Let ABC be a similar elliptic quadrant, in which there is inscribed a circle DEF of a given magnitude; then, if CA, CB , the semi-axes of this ellipse, be found, it is evident that e, f the points at which the circle touches the axes of the given ellipse may also be found; for, since the circle DEF is given in magnitude, the lines CE, CF are given in magnitude, each being equal to its radius, therefore, if the semi-axes CA, CB be determined, they will be divided at E and F into given segments; but the elliptic quadrants abc, ABC being similar, the semi-axes cb, CB will be similarly divided at f and F , therefore the ratio of cf to fb is given, and cb being given the point f may be found. In like manner it will appear that the point e may be found; but when the points at which the circle touches the axes are determined, the method of inscribing the circle is obvious. We proceed to investigate the semi-axes AC, BC .

Let G be the centre of the circle EDF . Join DG cutting the axes in H and K , then DHK will be a normal to the curve, therefore by a known proposition in Conics, HK is to HD as the square of the eccentricity to the square of the semi-transverse axis, which ratio is given, seeing it is the same as that of the like quantities in the given ellipse abc . In GD take L so that GK may be to GL in the same given ratio of HK to HD ; then $HK : HD :: HG$

$\therefore HG : GL = HD$; moreover the point G , and the line CK being both given by position the point L is in a straight line given by position; let this line be NQ .

Take $GM = DL$, then $GL = DM$, and $GL - HD = DM - HD = HM$; hence the proportion $HK : HD :: HG : GL - HD$ becomes $HK : HD :: HG : HM$; now the ratio of HK to HD being given, as already shewn, the ratio of HG to HM is also given; but the point G and the line CH are both given by position, therefore the point M is in a straight line given by position: Let this line be NR .

We have now found that DG passes through a given point G and meets two lines NQ , NR , both given by position, in L and M , so that $DL = GM$, hence it appears that the *Locus* of the point D is a hyperbola which passes through G , and has NQ , NR for its asymptotes; but D is also in the circumference of a given circle, therefore the point D , and the position of the normal DG are both determined.

Through D draw a perpendicular to the normal meeting the axes produced in S and T , this line, which is evidently a tangent to the curve at D , will be given by position, therefore the points S , T are both given. Draw DX , DY perpendiculars to the axis, and the points X , Y will also be evidently given. Now, from the nature of the ellipse, the semi-transverse CB is a mean proportional between CT and CY , which lines have been shewn to be both given in a magnitude, therefore the semi-transverse axis is also given in magnitude. In like manner it appears that the semi-conjugate axis CA , which is a mean proportional between CS and CX , is given in magnitude, but the semi-axes AC , BC being once found we have already shewn that the whole of the solution is obvious.

Solutions to this question were also received from Messrs. Geo. Roy, Marrat, and Whitley.

XV. QUESTION 285, answered by Mr. Swale.

Fig. 646, pl. 91. The base and vertical angle being given, the circumscribing circle from thence becomes known; let this circle be described, in which apply the chord AB equal to the given base of the triangle, draw the diameter FH to bisect AB in E , and join FB . Upon FH produced take FN equal to the given aggregate of the sum of the sides and line bisecting the vertical angle: then produce NF to R in such a manner that $FR = RN$

$= FB \times (AB + FB)$; to AB apply $FL = FR$, which produce till it cuts the circle in C, join AC, BC, and ABC is the triangle required.

DEMONSTRATION. The triangles ACL and FLB are similar, and CL bisects the angle ACB,

therefore $FL : FB :: AB : AC + BC$,
whence $FL \times (AC + BC) = FB \times AB$;

Also $FL : FB :: FB : FC$,

whence $FL \times FC = FB^2$, and by adding these together

$FL \times (AC + BC + FC) = FB \times (AB + FB)$.

But by the constr. $FR \times RN = FL \times RN = FB \times (AB + FB)$. Consequently $RN = AC + BC + FB$, and by taking away $FR = FL$, there will remain $FN = AC + BC + LC$, the given aggregate of the sum of the sides and line bisecting the vertical angle; therefore the triangle ABC is that required.

Thus it was answered by Messrs. Cunliffe and Whitley.

XVI. QUESTION 286, answered.

Mr. Gregory, the proposer, informs us that the case exhibited for consideration in this question is the same as one of those described by Dr. Desaguliers, in the Philosophical Transactions, No. 407, or abridgment Vol. VI. p. 307. He also finds that the same case is considered in S. Clark's Mechanics, and some later Treatises on that subject, a circumstance of which he was not aware, at the time he proposed the question.

The solution is deduced from very obvious principles. For the oblique force DP (fig. 534, pl. 28.) is resolvable into two others, one as CD perpendicular to the horizon, and the other equal to CP, and parallel to the horizon; this latter force is also parallel to the beam FC which has no tendency to turn it round its centre of suspension F. The force DC then is the only effective force, and must, because action and re-action are equal, be considered both acting upwards at the point P, and downwards at the point D or C. Therefore the effect of the oblique thrust DP will be represented by $(CF \times CD) - (FP \times CD)$, and this effect will be shewn in the motion of the scale D downwards.

Now, rad. : fine $\angle DPC :: DP : DC$;
that is $1 : .8660254 :: 8 : 6.9282032$ stones perpendicular force. And
 $(CF - PF) \times CD = .6 \times 6.9282032 = 4.15692192$ stones, additional weight, which must be added to W in order to counter-balance the oblique thrust DP.

Had

Had P been beyond C; with respect to F the fulcrum, then an oblique thrust, as DP, would have pushed the arm FC upwards; and this would be counter-balanced by taking away from the weight W, a weight proportional to $(FP - FC) \times CD$.

Mr. Marrat also favoured us with a solution to this question.

XVII. QUESTION 287, answered by Mr. Cunliffe.

Let P and r denote the same things as in my solution to Question 287; and n the time required.

Then after the first quarterly payment the debt will be denoted by

$$Pr - I,$$

after the second by $Pr^2 - r - n$,

after the third by $Pr^3 - r^2 - 2r - 3$,

after the fourth by $Pr^4 - r^3 - 2r^2 - 3r - 4$;

and therefore after the n th quarterly payment the debt will be denoted by

$$Pr^n - r^n - 1 - 2r^n - 2 - 3r^n - 3 - 4r^n - 4 \text{ &c.} - n \\ = r^n \times \left\{ P - \left(\frac{1}{r} + \frac{2}{r^2} + \frac{3}{r^3} + \frac{4}{r^4} + \text{ &c. } \frac{n}{r^n} \right) \right\}.$$

And by the said solution

$$\frac{1}{r} + \frac{2}{r^2} + \frac{3}{r^3} + \frac{4}{r^4} + \text{ &c.} + \frac{n}{r^n} = \frac{r^{n+1} + n - (n+1)r}{r^n \times (r-1)^2}$$

$$\text{Wherefore } r^n \times \left\{ P - \left(\frac{1}{r} + \frac{2}{r^2} + \frac{3}{r^3} + \frac{4}{r^4} + \text{ &c. } \frac{n}{r^n} \right) \right\}$$

$$= Pr^n - \frac{r^{n+1} + n - (n+1)r}{(r-1)^2}$$

$$= \frac{Pr^n + n - (2P+1) \times r^{n+1} + Pr^n + (n+1) \times r - n}{(r-1)^2}$$

$$= \frac{r^n \times \left\{ Pr^n - (2P+1)r + P \right\} + (n+1) \times r - n}{(r-1)^2}$$

And this expression is to be a maximum by the question,

or

$$\text{or } r^n \times \{Pr^n - (2P + 1)r + P\} + (n + 1) \times r - n$$

is to be a maximum; wherefore putting its fluxion = 0, and dividing by n , there will be had

$$\{Pr^{n-2} - (2P + 1) \times r^{n-1} + P r^n\} \times \text{h.l.}(r) + r - 1 = 0,$$

which when properly reduced gives

$$r^n = \frac{r - 1}{\{r - P \times (r - 1)\} \times \text{h.l.}(r)} = g,$$

whence again $n = \text{h.l.}(g) \div \text{h.l.}(r) = 12.70726$.

XVIII. QUESTION 288, answered by Mr. Cunliffe.

Let a denote the diameter of the circle, whose chord is l , and versed sine h ; and c the diameter of the circle, whose chord is b , and versed sine h . Also let x denote the perpendicular distance of any section of the groin parallel to the base from the vertex. The sides of the said section will be denoted by $2\sqrt{(ax - x^2)}$ and $2\sqrt{(cx - x^2)}$.

And from the nature of the figure and what is done at Art. 165. Vol. 1st. Simpson's Fluxions,

$$\left. \begin{aligned} & 4\sqrt{(ax - x^2)} \times \frac{\frac{1}{2}ax}{\sqrt{(ax - x^2)}} \\ & + 4\sqrt{(cx - x^2)} \times \frac{\frac{1}{2}cx}{\sqrt{(cx - x^2)}} \end{aligned} \right\} = 2ax + 2cx, \text{ is the fluxion}$$

of the convex surface; the fluent of which is $2ax + 2cx = 2x(a + c)$, and needs no correction, as the expression vanishes when $x = 0$; writing h for x the expression becomes $2h(a + c)$.

Now by the property of the circle

$$a = (\frac{1}{4}l^2 + h^2) \div h = \frac{241}{4} \text{ and } c = (\frac{1}{4}b^2 + h^2) \div h = 40;$$

wherefore $2h(a + c) = 862$, the convex surface of the groin.

Again, from what is delivered at Art. 155. Vol. 1. Simpson's Fluxions,

$$4x\sqrt{(ax - x^2)} \times \sqrt{(cx - x^2)} = 4x\sqrt{\{ac - (a + c)x + x^2\}} =$$

$$=\text{the fluxion of the solidity}=\frac{4acxx-4(a+c)x^2x+4x^3x}{\sqrt{\{ac-(a+c)x+x^2\}}}$$

by throwing the surd into the denominator.

And the fluent thereof when properly corrected is

$$\begin{aligned} & \left\{ \frac{(a+c)^2}{2} - \frac{4ac}{3} \right\} \sqrt{(ac)} + \frac{4x^2}{3} \sqrt{\{ac-(a+c)x+x^2\}} \\ & - \frac{(a+c)x}{3} \sqrt{\{ac-(a+c)x+x^2\}} \\ & - \left\{ (a+c)^2 - \frac{4ac}{3} \right\} \sqrt{\{ac-(a+c)x+x^2\}} \\ & + \left\{ ac(a+c) - \frac{(a+c)^3}{4} \right\} \times \text{h.l.} \left\{ \frac{\frac{a+c}{2}x - \sqrt{\{ac-(a+c)x+x^2\}}}{\frac{a+c}{2} - \sqrt{(ac)}} \right\} \end{aligned}$$

and writing h in the place of x , the expression becomes

$$\begin{aligned} & \left\{ \frac{(a+c)^2}{2} - \frac{4ac}{3} \right\} \sqrt{(ac)} + \frac{4h^2}{3} \sqrt{\{ac-(a+c)h+h^2\}} \\ & - \frac{(a+c)h}{3} \sqrt{\{ac-(a+c)h+h^2\}} \\ & - \left\{ (a+c)^2 - \frac{4ac}{3} \right\} \sqrt{\{ac-(a+c)h+h^2\}} \\ & + \left\{ ac(a+c) - \frac{(a+c)^3}{3} \right\} \times \text{h.l.} \left\{ \frac{\frac{a+c}{2}h - \sqrt{\{ac-(a+c)h+h^2\}}}{\frac{a+c}{2} - \sqrt{(ac)}} \right\} \end{aligned}$$

And this is the correct expression for the solid content or solidity of the groin. By a careful calculation, the numerical value of the solidity of the groin from the preceding expression is found to be 1483.688422 cubic inches.

XIX. QUESTION 289, answered by Mr. I. T. M'Donald.

LEMMA. The locus of a point within a given trapezium, whence perpendiculars demitted on the sides are together equal to a given length, is a right line given by position.

DEMON.

DEMON. Let $ABCD$ (fig. 648, pl. 32.) be a given trapezium. At the distance DE , or CH = the given sum of 4 perpendiculars draw EF , $GH \parallel$ to AD , BC , meeting the other sides produced in the points I , F , G , K , and bisect the angles at those points by right lines meeting the sides in L , M , N , O ; join LM and NO intersecting BC in P and AD in Q ; draw PQ and it is the locus. For, through L and M draw RS , TV parallel and equal to DE ; $LW \perp$ to CD , and $MY \perp$ to AB ; then because the $\angle K$ is bisected, $LW = LS$ and $LW + LR (= MT + MY) = DE$, and LM is the locus of a point, whence perpendiculars demitted on the 3 sides AB , AD , CD are together equal to the sum of the perpendiculars on the 4 sides; which is thus proved: through any point p in LM draw $qr \parallel DE$, also $ps \parallel AB$, $pn \perp$ to AB and $po \perp$ to CD , also $Md \parallel EF$; then $LS - MV = LW - MY = Ld$, and $pr - MV = ph$.

But by sim. fig. $LW : MY :: po : Ms$;
dividendo $LW : Ld :: po : ph$ (by sim. Δ s).

Hence po exceeds Ms as much as pr exceeds MV ,
and $pn + po = MY + ph = pr$; theref. $pr + pn + po = qr$ or DE .

In like manner it may be proved that ON is the locus of a point whence perpendiculars demitted on AB , BC , CD , are together equal to CH or DE . Further, through any point Q' in PQ , draw $ad \parallel AD$ meeting DE in e ; then it is too manifest to need any demonstration here, that if $aBCd$ were the given trapezium and eE the given sum of the perpendiculars, that Q' would be the position of Q , $O'N'$ of ON , and that perpendiculars from Q' on the sides AB , BC , CD , would together be equal to eE , to which add eD or Qf , and DE is the sum of the perpendiculars on the 4 sides demitted from the point Q' ; and the same may be proved of any other point in the line PQ . *Q. E. D.*

The locus PQ (fig. 649, pl. 32.) of the required point being determined for the sum of the perpendiculars, by the preceding Lemma; next find two right lines RY , RZ (by Prop. XVI. of Stewart's Gen. Theo.) that will be given by position such that the sum of the squares of perpendiculars demitted from any point on the sides of the trapezium may be equal to 4 times the sum of the squares of perpendiculars from the same point on RY , RZ , together with a given space, viz. the sum of the squares of the perpendiculars Rs , Rt , Rv , Rw (Vide Lowry's Sol. pa. 329, vol. I.) The problem will then be reduced to this; to find a right line given by position within a given angle YRZ , such that the sum of the squares of perpendiculars from that point on RY , RZ may be equal to a given space, viz. $\frac{1}{2}$ of the difference between the sum of the squares Rs , Rt , Rv , Rw , and the sum of the squares, of perpendiculars from the required point on the sides of the trapezium.

perium which may be done thus: From the point of intersection a , of PQ and RY, demit $ab \perp$ to RZ, produce YR till $Rc = ab$, draw Pd also \perp to RZ, and $Pe \parallel ac$ meeting $Rc \perp$ to ac in e , and produce it till $cf = Pd$; join cf , and take $Rg =$ side of a square equal to the given space; lastly draw $gO \parallel cY$ meeting PQ in O, and O is the point required to be found.

For if Ok , Oi , be made \perp to RY, RZ, it is evident from the construction that $Ok = gk$, and $Ok = Rk$, and $Rk^2 + gk^2 = Ok^2 + Oi^2 = Rg^2 =$ given space.

Moreover, by the abovementioned proposition $Rs^2 + Rr^2 + Rv^2 + Rw^2 + 4Ok^2 + 4Oi^2 = On^2 + Op^2 + Oq^2 + Or^2 =$ the sum of the squares of the 4 perpendiculars given per question.

SCHOL. The sum of the squares of Rs , Rr , Rv , Rw is a minimum.

XX. QUESTION 290, answered by Mr. John Dawes.

From the data are found the latitude $= 18^{\circ} 53' 42''$ and the sun's declination $= 19^{\circ} 47' 25''$.

When the azimuth circle ZON (fig. 645, pl. 31.) becomes a tangent to the parallel of declination d , d , that point is the position of the sun when a maximum in azimuth. In the right angled triangle POZ there are given $PZ =$ co-latitude and $PO =$ co-declination to find the angle $OPZ = 17^{\circ} 58' 4''$; hence the required time is 10h. $48' 7''$ $44''$.

The same, by Captain Geo. Gorry.

It appears from Art. 137, of Mr. Gregory's Astronomy, that when the sun's declination is equal to the difference between the co-latitude and 18° , then the parallel of declination will just touch the crepusculum circle, and the twilight will just continue all night. Hence $87^{\circ} 47' 25''$ (co-latitude of Cambridge) $- 18^{\circ} = 19^{\circ} 47' 25''$ north declination of the sun at the commencement of the period when twilight continues all night, this answers pretty well to May 20th 1809. The latitude of the place where the

sun's maximum azimuth from the north is sought, is $\frac{37^{\circ} 47' 25''}{2}$

$= 18^{\circ} 53' 42''$. This latitude is therefore less than the sun's declination; and the case corresponds with what is shewn at Art. 185, of the work above referred to; where it appears that the azimuth circle ZO will touch the parallel of the sun's declination in the point O and there will be given in the spherical triangle ZOP, right angled at O, the co-latitude $ZP = 71^{\circ} 6' 17''$, and the co-declination $OP = 70^{\circ} 12' 35''$, to find ZPO the hour angle from noon; that is, $\text{tang. } ZP : \text{tang. } OP :: \text{radius} : \text{cosine of } P = 17^{\circ} 58' 4''$; this converted into time gives 1h. 11m. 52s. 16t. time from noon; therefore 10h. 48m. 7s. 44t. is the time in the morning when the azimuth from the north is the greatest, at the given day and place.

The same, by Tyro Philomatheticus.

It is manifest that the beginning of the period mentioned in the question will be when the sun's declination is $= 37^{\circ} 47' 25''$ (co-lat. of Cambridge) — $18^{\circ} = 19^{\circ} 47' 25''$, and the latitude of the place is given $= 18^{\circ} 53' 42''$; therefore let HZHN be the meridian, HH the horizon, SP the axis, $\text{A} \& \text{A}'$ the equator, draw the parallel of declination dd' , and by Prob. XLV. Simpson's Problems, at the end of his Geometry, describe an azimuth circle to touch the parallel dd' , and the point of contact O will evidently give the sun's greatest distance from the north; then an hour circle being drawn through O will shew the time required. Now, because by spherics the radius $A'd'$ of the parallel dd' , is a tangent to the primitive HZP at d' , we have $A'd' = AP \times AS$, but $A'd' = AO$; therefore $AO^2 = AP \times AS$, whence AO is a tangent to the hour circle POS at O; but by Simpson's Geometry III. 8. Cor. 2. AO produced passes through the centre B of the azimuth circle ZON and consequently is perpendicular to ZO, and therefore ZOP is a right angle; hence we have, as cotang. lat. : cot. declin. :: radius : cosine of the hour from noon $= 17^{\circ} 58' 3'' \frac{1}{2} = 1\text{h. } 11\text{m. } 52\text{s. } 14\text{t.}$ the time required from noon.

It was also answered by Mr. Marrat.

XXI. QUESTION 291, answered by Quibus Elestrin.

Let ACD (fig. 647, pl. 81.) be a semi-circle, AC, CD, and DB arcs into which its circumference is subdivided. Draw the chords of these arcs and the radii CO, DO. The chords AC, S 2 CD,

CD ; and DB have obviously the same ratio as their halves; and these half chords are respectively the sines of the angles $\frac{1}{2}AOC$, $\frac{1}{2}COD$, and $\frac{1}{2}DOB$.

And $\frac{1}{2}AOC + \frac{1}{2}COD + \frac{1}{2}DOB =$ a right angle.

This being premised, put $AB = 2r$, $AC = x$, $DB = y$; the ratio of AC to CD that of r to b ; viz.

$AC : CD :: r : b :: 2r = AB : 2b$; whence

$2b \times AC = 2bx = AB \times CD$. Also let the given ratio of AC to BD be denoted by that of r to c ; viz.

$AC : BD :: r : c$, whence $r \times BD = c \times AC$, or $ry = cx$.

Then by Eu. I. 47. $BC = \sqrt{(4r^2 - x^2)}$; and $AD = \sqrt{(4r^2 - y^2)}$;

And by Emerson's Geometry, Book IV. Prop. 29, $BC \times AD = AB \times CD + AC \times CD$, which being expressed algebraically from what has been deduced is

$$\sqrt{(4r^2 - x^2)} \times \sqrt{(4r^2 - y^2)} = 2bx + xy,$$

and by squaring the equation

$$\{ (4r^2 - x^2) \times (4r^2 - y^2) \} = 4b^2x^2 + 4bx^2y + x^2y^2;$$

or $16r^4 - 4r^2(x^2 + y^2) + x^2y^2 \} = 4b^2x^2 + 4bx^2y + x^2y^2$;

or, $bx^2y + rx^2 + ry^2 + b^2x^2 = 4r^4$, and exterminating y by

means of the equation $ry = cx$ it becomes

$$\frac{bcx^2}{r} + (r^2 + b^2 + c^2) \times x^2 = 4r^4, \text{ from whence } x^2 \text{ may be}$$

found.

The same, by Scotiens.

Let ϕ and ψ denote two of the angles into which the right angle is to be divided; then the sines of the three angles required will be

$$\text{Cos. } (\phi + \psi), \text{ sin. } \phi, \text{ sin. } \psi.$$

So that, putting 1 , n , p to denote the given ratios, we have

$$\text{Cos. } (\phi + \psi) = n \text{ sin. } \phi = p \text{ sin. } \psi.$$

But $\text{cos. } (\phi + \psi) = \text{cos. } \phi \text{ cos. } \psi - \text{sin. } \phi \text{ sin. } \psi$, therefore substituting for $\text{sin. } \psi$ its value $\frac{n}{p} \text{ sin. } \phi$, and transposing

$$\text{cos. } \phi \text{ cos. } \psi = \frac{n}{p} \text{ sin. } \phi^2 + n \text{ sin. } \phi.$$

Hence,

Hence, squaring and substituting $1 - \sin. \phi^a$ for cos. ϕ^a , also $1 - \frac{n^a}{p^a} \sin. \phi^a$ for cos. ψ^a we have this equation

$$(1 - \sin. \phi^a) (1 - \frac{n^a}{p^a} \sin. \phi^a) = (\frac{n}{p} \sin. \psi^a + n \sin. \phi^a)^a$$

which by proper reduction and putting sin $\phi = x$ becomes

$$\frac{2n^a}{p^a} x^a + (n^a + \frac{n^a}{p^a} + 1) x^a - 1 = 0,$$

Or, putting $y = \frac{2}{x}$.

$$y^3 - (n^a + \frac{n^a}{p^a} + 1) y - \frac{2n^a}{p^a} = 0$$

a cubic equation wanting the second term and therefore ready to be resolved by known rules.

Ingenious solutions to this question were also received from Messrs. Cunliffe and Whitley.

XXII. QUESTION 292.

NOT ANSWERED.

XXIII. QUESTION 293, answered by Mr. Bazley, Bolton.

It is well known that the sum of n terms of the series

$$x + x^2 + x^3 + \&c. \dots x^{n+1} = \frac{x^{n+2} - x^2}{x - 1},$$

take the second fluxion and it becomes

$$1.2 + 2.3x + 3.4x^2 + 4.5x^3 + \&c. \dots n(n+1)x^{n-1}$$

$$= \text{the second fluxion of } \frac{x^{n+2} - x^2}{x - 1}$$

S. B.

$$= \left\{ \begin{array}{l} \frac{(n+1)(n+2)x^n - 2}{x-1} + \frac{2(x^{n+2} - x^n)}{(x-1)^2} \\ - \frac{2 \{ (n+2)x^{n+1} - 2x \}}{(x-1)^3} \end{array} \right\};$$

therefore the sum of n terms of the proposed series is

$$= x \left\{ \begin{array}{l} \frac{(n+1)(n+2)x^n - 2}{x-1} - \frac{2 \{ (n+2)x^{n+1} - 2x \}}{(x-1)^2} \\ + \frac{2(x^{n+2} - x^n)}{(x-1)^3} \end{array} \right\}.$$

GENERALLY. Let $x^m + x^{m+1} + x^{m+2} + \&c.$
 $x^{m+n-1} = s$

then $1.2.3 \&c. \dots m+2.3.4 \&c. \dots (m+1)x + 3.4.5 \&c. \dots (m+2)x^3$
 $+ 4.5.6 \&c. \dots (m+2)x^2 + \&c. \dots n(n+1)(n+2) \&c. \dots (n+n-1)x^{n-1}$
 is equal to the n th fluxion of s ; supposing $x = 1$.

The same, answered by Mr. Cunliffe.

$$\text{First } x^0 + x^1 + x^2 + x^3 + x^4 + \&c. \dots = \frac{x^n}{1-x};$$

$$\text{and } x^{n+2} + x^{n+3} + x^{n+4} + x^{n+5} + \&c. \dots = \frac{x^{n+2}}{1-x};$$

The latter series is evidently a continuation of the former after a leading terms; wherefore their difference will be

$$x^n + x^{n+1} + x^{n+2} + x^{n+3} + \&c. \text{ to } n \text{ terms} = \frac{x^n - x^{n+2}}{1-x};$$

the fluxion of this expression divided by x is
 $nx^{n-1} + 2x^{n-2} + 3x^{n-3} + 4x^{n-4} + 5x^{n-5} + \&c. \text{ to } n \text{ terms}$

$$= \frac{(n+1)x^{n+2} - (n+2)x^{n+3} + 2x - x^n}{(1-x)^2} = \frac{v}{(1-x)^2}, \text{ by putting}$$

$v =$

$$v = (n+1)x^{n+2} - (n+2)x^{n+1} + 2x - x^n.$$

Again taking the fluxion of the preceding expression and dividing by $\frac{x}{x}$ there will be had

$$1.2x + 2.3x^2 + 3.4x^3 + 4.5x^4 + \text{&c. to } n \text{ terms}$$

$$= \frac{\frac{xd}{x} \times (1-x) + 2xv}{(1-x)^2} = \frac{xd}{x(1-x)^2} + \frac{2xv}{(1-x)^2}.$$

Now by the substitution

$$v = (n+1)x^{n+2} - (n+2)x^{n+1} + 2x - x^n, \text{ taking the fluxion of this equation and dividing by } \frac{x}{x} \text{ gives}$$

$$\frac{xd}{x} = (n+1)(n+2)x^{n+2} - (n+1)(n+2)x^{n+1} + 2x - 2x^n;$$

wherefore $1.2x + 2.3x^2 + 3.4x^3 + 4.5x^4 + \text{&c. to } n \text{ terms}$

$$= \frac{xd}{x(1-x)^2} + \frac{2xv}{(1-x)^2}$$

$$= \left\{ \begin{array}{l} \frac{(n+1)(n+2)x^{n+2} - (n+1)(n+2)x^{n+1} + 2x - 2x^n}{(1-x)^2} \\ \quad + \frac{2(n+1)x^{n+3} - 2(n+2)x^{n+2} + 4x^2 - 2x^3}{(1-x)^2} \end{array} \right.$$

$$= \left\{ \begin{array}{l} \frac{2x - (n+1)(n+2)x^{n+1}}{(1-x)} \\ \quad + \frac{2(n+1)x^{n+3} - 2(n+2)x^{n+2} + 4x^2 - 2x^3}{(1-x)^2} \end{array} \right.$$

$$= \left\{ \begin{array}{l} \frac{2x - (n+1)(n+2)x^{n+1}}{(1-x)} \\ \quad + \frac{2(n+1)x^{n+3} - 2(n+2)x^{n+2} + 4x^2 - 2x^3}{(1-x)^2} \end{array} \right.$$

Which is a correct expression for the sum of n leading terms of the proposed series.

The same, answered by Tyro-Philomatheticæ.

This question is a particular case of Prob. XXXI. page 425. Emerson's method of Increments, wherein it is required to find S the sum of n terms of the series

$Ma + Na^2 + Oa^3 + Pa^4 &c.$ Putting v for the coefficient of a in the $(n+1)$ th term he gets

$$S = \frac{a^{n+1}v}{a-1} - \frac{a^{n+2}v}{(a-1)^2} + \frac{a^{n+3}v}{(a-1)^3} - \frac{a^{n+4}v}{(a-1)^4} &c.$$

v, v, v , and v being the 1st, 2nd and 3d increments of v .

In the example before us $a = x$, $v = (n+1)(n+2)v$, $v = 2(n+2)$, $v = 2$, and $v = 0$; therefore the sum of n terms is

$$S = \frac{(n+1)(n+2)x^{n+1}}{x-1} - \frac{2(n+2)x^{n+2}}{(x-1)^2} + \frac{2x^{n+3}}{(x-1)^3};$$

but this requires correction, for when $n = 0$,

$$\text{then } S = \frac{2x}{x-1} - \frac{4x^2}{(x-1)^2} + \frac{2x^3}{(x-1)^3};$$

whence the sum corrected is $\frac{2(n+1)(n+2)x^{n+1}}{x-1}$

$$- \frac{2(n+2)x^{n+2}}{(x-1)^2} + \frac{2x^{n+3}}{(x-1)^3} = \frac{2x}{x-1} + \frac{4x^2}{(x-1)^2} - \frac{2x^3}{(x-1)^3};$$

this reduced to a common denominator, gives

$$S = \frac{2(n+1)x^{n+3} - 2n(n+2)x^{n+2} + (n+1)(n+2)x^{n+1} - 2x}{(x-1)^3}$$

If x be a fraction the theorem will be better expressed with the signs changed.

This Question was ingeniously answered by Messrs. Limenus, Marrat, Quibus Flestrin, and Thornoby.

XXIV. QUESTION 294, answered by Mr. Cunliffe.

A N A L Y S I S. Let $ABCD$ (fig. 651, pl. 32.) be the trapezium, its diagonals AC, BD intersecting each other in I , and suppose the latter divides the former in the given ratio. Draw Im, Ip , respectively parallel to BC, AB , and terminating in those lines in m and p . Also draw In, Iq , respectively parallel to DC, AD , and terminating in those lines in n and q . Then it is obvious that the side AB is divided at m in the given ratio of the parts of the diagonal AI , IC , and therefore Bm is given, and for the same reason, Bp is given, or known, as likewise Dn and Dq .

Then by prop. 36, Lawson's Theorems.

$$BI^* + AI \times IC = BA \times Bm + BC \times Bp \\ = \text{a given magnitude; and}$$

$$DI^* + AI \times IC = DA \times Dn + DC \times Dq \\ = \text{a given magnitude.}$$

And the difference of these will give

$DI^* - BI^* = \text{a given magnitude.}$ Now with the centres q and C , and the radii qI, CB let two circles be described; then the question is evidently reduced to what follows; viz. From the given point D to draw a right line to cut the circles whose radii are qI , and CB in I and B so that $DI^* - BI^*$ may be of a given magnitude.

Quinibus Flestrin also answered this question.

XXV. QUESTION 295, answered by Scoticus.

Fig. 675. Pl. 33. Suppose a line drawn through the given point P as required. Through the same point draw any other line given by position, cutting the given lines $AL, BM, CN, DO, \&c.$ in $a, b, c, d, \&c.$ Then the lines $Pa, Pb, Pc, Pd, \&c.$ will be given in magnitude. Join $PB, PC, PD, \&c.$ cutting Aa , one of the given lines in $\beta, \gamma, \delta, \&c.$ The lines $PB, PC, PD, \&c.$ will be given by position, and therefore the points $\beta, \gamma, \delta, \&c.$ will also be given.

From similar triangles, $Pa : Pb :: P\beta : PB :: AL : BM$,

$$\text{therefore } BM = \frac{Pb}{Pa} \cdot AL, \text{ and } BM^* = \frac{P\beta}{Pa} \cdot AL^*.$$

In

In like manner $CN^* = \frac{Pc^*}{Pa^*} \cdot yL^*$, also $DO^* = \frac{Pd^*}{Pa^*} \cdot \delta L^* \text{ &c.}$

Now by hypothesis

$AL^* + BM^* + CN^* + DO^* + \text{ &c.} = \text{a given space,}$
therefore also

$AL^* + \frac{Pb^*}{Pa^*} \cdot \beta L^* + \frac{Pc^*}{Pa^*} \cdot yL^* + \frac{Pd^*}{Pa^*} \cdot \delta L^* + \text{ &c.} = \text{a given space.}$

But it appears from Dr. Stewart's XV General Theorem, (See Math. Rep. Vol. I. Pa. 349.) that a point X may be found in \mathbb{A}^2 , such, that wherever L be taken

$$\left. \begin{array}{l} AL^* + \frac{Pb^*}{Pa^*} \cdot \beta L^* + \frac{Pc^*}{Pa^*} \cdot yL^* \\ + \frac{Pd^*}{Pa^*} \cdot \delta L^* + \text{ &c.} \end{array} \right\} = \left\{ \begin{array}{l} \frac{Pa^* + Pb^* + Pc^* + Pd^* + \text{ &c.}}{Pa^*} \cdot XL^* \\ + \text{ a given space:} \end{array} \right\}$$

Hence it is evident that

$$\frac{Pa^* + Pb^* + Pc^* + Pd^* + \text{ &c.}}{Pa^*} \cdot XL^* = \text{a given space.}$$

Therefore XL^* and consequently XL is given. Thus the construction of the problem is reduced to the determination of the point X , which may be found as in the place already quoted.

XXVI. QUESTION 296, answered by Mr. Caulliffe.

Put $m^2 - n^2 = x$, and $2mn = y$, then

$x^2 + y^2 = (m^2 + n^2)^2$ which is a rational square.

It therefore only remains to find such a relation of m and n as shall make

$$\begin{aligned} x^2 + xy + y^2 &= (m^2 + n^2)^2 + 2mn \times (m^2 - n^2) \\ &= m^4 + 2m^2n^2 + n^4 - 2m^2n^2 + x^2 = \text{a square:} \end{aligned}$$

Assume $m^2 + mn + n^2$ for its root, then will

$$\begin{aligned} m^4 + 2m^2n^2 + 2m^2n^2 - 2m^2n^2 + n^4 &= (m^2 + mn + n^2)^2 \\ &= m^4 + 2m^2n^2 + 3m^2n^2 + 2m^2n^2 + n^4; \end{aligned}$$

Whence $m^2n^2 = -4mn^2$, and $m = -4n$.

But this relation of m and n would give the value of y negative; therefore in order to obtain positive values for both x and y , put $m = v - 4n$, then will

$$\begin{aligned} x^2 + xy + y^2 &= (m^2 + n^2)^2 + 2mn \times (m^2 - n^2) \\ &= v^4 - 14v^2n^2 + 74v^2n^2 - 178v^2n^2 + 169n^4 = \text{a sq.} \end{aligned}$$

Assume

Assume $(v^2 - 7vn - 13n^2)$ for the root of the last expression, that is, put

$$v^4 - 14v^3n + 74v^2n^2 - 178vn^3 + 169n^4 = (v^2 - 7vn - 13n^2)^2$$

$$= v^4 - 14v^3n + 28v^2n^2 + 182vn^3 + 169n^4;$$

$$\text{whence } 51v^2n^2 = 360n^3, \text{ or } v = \frac{120n}{17};$$

$$\text{put } n = 17, \text{ then } v = 120, \text{ and } m = v - 4n = 52;$$

$$\text{whence } x = m^2 - n^2 = (52)^2 - (17)^2 = 2415$$

$$\text{and } y = 2mn = 52 \times 34 = 1768.$$

A solution to the following question may be easily effected from what has been done, viz. To find two fractions of such a kind that both their sum, and sum of their squares may be a rational square; also if either of them be added to the square of the other, the sum shall be a rational square; and furthermore if their product be subtracted from either of them, the remainder shall be a rational square.

Let the two fractions be denoted by $\frac{x}{x+y}$ and $\frac{y}{x+y}$; for their sum will obviously be 1, which is a square number, and the sum of their squares will be $\frac{x^2 + y^2}{(x+y)^2}$, which is to be a square, therefore $x^2 + y^2$ must be a square, and if either of them be added to the square of the other the sum will be $\frac{x^2 + xy + y^2}{(x+y)^2}$ which is to be a square, therefore $x^2 + xy + y^2$ must be a square. The two remaining conditions will be answered by the assumption or notation, viz. if their product be taken from either of them, the remainder shall be a square. The question is therefore reduced to finding such values of x and y as shall make $x^2 + y^2$, and $x^2 + xy + y^2$ both rational squares, which, from what is before done, will be when $x = 2415$, and $y = 1768$, and the required fractions will be $\frac{x}{x+y} = \frac{2415}{4183}$ and $\frac{y}{x+y} = \frac{1768}{4183}$.

Neat solutions were received from Limenus and Whitley.

XXVII. QUESTION 297, answered by Mr. J. H. Swale.

Fig 653. Pl. 32. CONSTR. Join PQ and make the $\triangle PQR$ of the given magnitude; through R draw the indefinite right line

RG

RG parallel to RQ ; Then through Q , by Prob. 37, Simpson's Geometry, draw the right line $QGBC$ cutting the lines RG , AB , and AC in G , B , and C , so that BC may be equal to QC , and the thing is done.

DEMONSTRATION. Draw the lines PG , PB , and PC . Then $BC = QG$ by construction; therefore the $\triangle BPC \cong \triangle QPG = \triangle QRP$, the given magnitude. *Q. E. D.*

And thus nearly are the answers given by Messrs. Cunliffe, M'Donald, and W. Smith.

XXVIII. QUESTION 298, answered by Mr. J. T. M'Donald.

CONSTRUCTION. Fig. 1684. Pl. 33. Biseect AP in H , and take HI such that $\text{rect. PI} \cdot \text{IH} = \text{rect. BP} \cdot \text{PH}$; draw $ID \parallel$ to BC meeting AC in D , through which draw PDE .

DEMONSTRATION. Biseect the base AB by CG , and \parallel thereto draw CK ; also draw EQ and $DF \parallel$ to AB , and join HL which passes through D . Then because DEF is a maximum, its half DML is also a maximum. If not, through any other point d in AC draw Hde , and $fdg \parallel$ and equal to MD , meeting KD produced in g ; biseect KG in N , and draw $Nq \parallel CG$ meeting DM in O , fg in o , DL in p , and ke in q , also draw $ghi \parallel$ and equal to DL , and $ir \parallel$ and equal to Dg or Oo , and $dmn \parallel$ and equal also to Dg meeting DL in m . Now by Construction

$$PI : PB :: HP \text{ or } HA : HI; \text{ dividendo,}$$

$$PI : DF :: HA : AI, \text{ or,}$$

$$PI : DM :: HA : AK, \text{ and}$$

$$HK : KN :: HA : AK; \text{ convertendo,}$$

$$HK : HN :: HA : HK = QL : DM = CL : CM, \text{ theref.}$$

$$HK : HN = CL : CM, \text{ and consequently}$$

$$Dk : pq = dm : dn \text{ or } Oo;$$

but dm is greater than Dk , and theref. Oo or ir exceeds pq .

Then (Euc. I. 35), the parallelograms $DMfg$, $DLeg$ are equal, from which if the common triangle Dfg be taken away and Lgh added, we have the $\triangle DML$ equal to ghk which exceeds the $\triangle dfe$ as much as hkg is less than gfk . Further draw any other line Hvy below D meeting Nq in x and UK in a , and draw $vcw \parallel DM$ meeting Nq in c and DK in b ; then

$$Da : pa :: HK : HN :: HA : HK :: CL : CM,$$

which, because $\angle Cuy$ is greater than CDL is a less ratio than that of $Cy : Cw$ or $Da : Oc$; therefore pa is greater than Oc , and the

the space LDay than MDown, and DML than vary. Hence the triangle DML and consequently DEF is a maximum.

Q. E. D.

The same, by Mr. Wm. Smith, the Proposer.

LEMMA. 1st. Let ABC (fig. 657, pl. 32.) be any Δ , P a given point in BA produced, draw any line $\overset{\text{P}}{\text{D}}\overset{\text{E}}{\text{F}}$ to cut AC, BC in D and E respectively, and draw $\overset{\text{E}}{\text{F}}\overset{\text{G}}{\text{H}}$ \parallel AB meeting AC in F. Then if AQ be taken in the right line CA equal to DF and PQ be joined, meeting $\overset{\text{E}}{\text{F}}\overset{\text{G}}{\text{H}}$ in L; the locus of all the points L will be a parabola whose diameters are \parallel to AC, and the parameter (namely of the diameter bisecting BA) of which is to CH (PH being \parallel BC and meeting CA in H) as (joining PC and drawing $\overset{\text{E}}{\text{W}}\overset{\text{G}}{\text{H}}$ \parallel AC to meet it in W) $\overset{\text{F}}{\text{E}}\overset{\text{G}}{\text{H}}$ is to $\overset{\text{F}}{\text{C}}\overset{\text{E}}{\text{W}}$.

DEMONSTRATION. By the similar Δ s PDH, EDC and PAD, EDF the rest. $\text{HD}\cdot\text{DF} = \text{rect. AD}\cdot\text{DC}$ therefore (producing EL to meet PH in Y and joining PY meeting EL in O) by parallels rest. $\text{YE}\cdot\text{EO} = \text{KE}\cdot\text{EW}$, that is, since $\text{AQ} = \text{DF}$, the rest. $\text{YE}\cdot\text{KL} = \text{rect. KE}\cdot\text{EW}$. Therefore $\text{YE}\cdot\text{LK} : \text{BK}\cdot\text{KA} :: \text{KE}\cdot\text{EW} : \text{BK}\cdot\text{KA} :: \text{FC}\cdot\text{EW} : \overset{\text{F}}{\text{E}}\overset{\text{G}}{\text{H}}$; but per Emerson's Conics, Prop. 25th, Bk. IIIId. (P being the parameter, &c.) $\text{P}\cdot\text{LK} = \text{BK}\cdot\text{KA}$; therefore $\text{P} : \text{YE} :: \overset{\text{F}}{\text{E}}\overset{\text{G}}{\text{H}} : \text{FC}\cdot\text{EW}$. Therefore the locus of L is a parabola, whose parameter is to HC (YE) :: $\overset{\text{F}}{\text{E}}\overset{\text{G}}{\text{H}} : \text{FC}\cdot\text{EW}$. Q. E. D.

LEMMA 2d. Let P be a given point in the side SA produced of any given Δ SAR. Then I say, if PQL be drawn meeting AR, RS in Q and L respectively, and AL be joined, the Δ AQL will be a maximum, when (drawing LG \parallel AS meeting AR in G) $\text{AQ} = \text{RG}$.

DEMONSTRATION. Draw PZ \parallel AR meeting SR in Z, PV \parallel SR meeting RA in V, and ZX \parallel PA meeting AR in X. Then by similar Δ s PLZ, PQV, rest. $\text{ZL}\cdot\text{QV} = \text{rect. PZ}\cdot\text{PV}$, and therefore the rest. $\text{XG}\cdot\text{VQ} = \text{rect. AV}\cdot\text{IZ}$, that is, wheresoever PQL be drawn the rest. XG·VQ is given. Again the Δ ALQ = $\frac{1}{2}\text{AP}\cdot\text{GQ}$ ($\text{LK} = \text{QA}$), therefore, when the Δ AQL is a max. the line GQ is a max. or the sum of XG and VQ a minimum, but the rest. XG·VQ is given, therefore XG + VQ is a minimum, when XG = VQ, and when XG = VQ, therefore the line GQ and the Δ AQL are both the greatest possible, but by \parallel s XR = AV, therefore RG = AQ. Q. E. D.

Hence the problem may be thus constructed:

Draw any line $\overset{\text{f}}{\text{e}}\overset{\text{w}}{\text{f}}$ \parallel AB and $\overset{\text{e}}{\text{w}}\overset{\text{f}}{\text{c}}$ \parallel AC meeting PC in w, determine the line Cd, such that twice Cd may be to CH :: $\overset{\text{f}}{\text{e}}\overset{\text{w}}{\text{f}} : \overset{\text{f}}{\text{c}}$.

ex. Bisect AB in M, and produce PM to K, so that drawing KE \parallel AC, the reft. FK KM may be equal to Cd·KE (the method of doing which is so simple that it need not be detailed); join PE meeting AC in D, and draw EF \parallel AB, so shall DEF be the maximum Δ required.

DEMONSTRATION. On AB describe a parabola, as in Lemma 1st, the parameter of whose diameter to the ordinate AB may be equal to twice CL, and its diameter \parallel AC. Produce EK to meet PC, and the parabola in W and L respectively, draw the tangent SLR meeting AB, AH in S and R respectively, draw also LG \parallel AB; join PL (meeting AB in Q) and AL, and through M the middle of AB draw INMaggry meeting EF, ED, AB, AL, PL, LG the parabola and tangent SR in the points I, N, M, a, q, g, x, and y respectively. Then by construction, reft. PK. KM \equiv KE Cd: but PK is to KE as FE : FD. Therefore reft. FE·EI \equiv FD·Cd, that is, by ||s, Lemma 1st, and construction reft. GL·Lg \equiv AQ·Cd; and therefore since GL : AQ :: $g^2 L \cdot aq : g^2 L^2 \equiv aq \cdot Cd$, that is, $g^2 L^2 \equiv aq \cdot \frac{1}{2} P$ (Parameter) but $g^2 L^2 \equiv g^2 x \cdot P$, therefore, aq ($=$ twice gx) \equiv (per nature of the tangent to the parabola) yg , and thence AQ \equiv RG. Therefore, per Lemma 2d, the Δ AQL is a maximum within the tangential triangle ARS, and consequently is a max. in the inscribed parabola or curve: but since AQ \equiv DF the Δ AQL is always \equiv to Δ EDF; therefore the Δ EDF is a maximum also. *Q. E. D.*

The same by Mr. John Wright, Jun. of Norley.

ANALYSIS. Suppose the thing done, and perpendicular to CB (fig. 658, pl. 32.) draw PK meeting AK drawn parallel to BC in K and BC in I; join CK, and through D, parallel to BC, let a right line be drawn, cutting AB in L, PK in G, and CK in S; demit SM perpendicular to BC, also draw LS cutting BC in V. Then by reason of parallel lines,

$$GK : KI :: LD : EC, \text{ and } GK : KI :: GS : IC,$$

and therefore, by equality of ratios,

$$GS : IC :: LD : EC, \text{ or } GS : LD :: IC : EC:$$

also, because of the sim. Δ s VMS, PGS; EDF, PLD, it will be VM : GS :: SM (GI) : PG :: EF : LD; wherefore VM : EF :: GS : LD :: IC : BC (*supra*) a given ratio, consequently the ratio of VM : EF is given; and because LS is parallel to BC, the triangle VSM has to the triangle EDF the same given ratio of VM to EF, therefore, when the triangle EDF is a maximum, the right angled triangle VSM will be a maximum also.

On

On PK describe the semicircle PYQK, cutting SL and CB produced in Q and Y; draw QI, also PQ cutting IY in R; and complete the parallelogram MSQH. Then, by similar triangles, $\Delta PGS : \Delta VSM :: PG^a : SM^a (QH^a)$

$$\therefore QG^a (PG \cdot GK) : HR^a ; \text{ that is,}$$

$HR^a : \Delta VSM :: PG \cdot GK : PG \cdot GS :: GK : GS$ a given ratio, and therefore when the triangle VSM is a maximum, HR^a will be a maximum, and consequently HR ; but when this is a maximum, the triangle RQI must be so; as is evident from the consideration of the similar triangles PIR and HQR, the side PI being constant. Now, if the tangent TN, terminating in IK and IY produced, be drawn to the circle at Q, it will readily appear, from either of the solutions of Question 595, Vol. III. of Hutton's Dianian Miscellany, that when TH is equal to RI, the triangle RQI is greater than any other which can be formed within the triangle TNI, by lines drawn from P and I, and it must evidently then be greater than any other which can be so formed within the semi-segment IKQY. Having therefore shewn that the triangle RIQ, and of consequence the required one EDF, is a maximum when $TH = RI$, let QK be joined, and, O being the centre of the semi-circle, draw the radius OQ; then the triangle QGK is manifestly similar to QRH, and hence $QG \cdot RH = GK \cdot QH$;

the triangle OGQ is also similar to THQ, and $OG \cdot QH = QG \cdot TH (QG \cdot RI) = QG^a - QG \cdot RH = PG \cdot GK - KG \cdot QH$;

therefore $PG \cdot GK = QH \cdot (OG + GK) = QH \cdot OK = PG \cdot OK - PI \cdot OK$;

or $PG \cdot OG = PI \cdot OK =$ a given magnitude. Whence the following

CONSTRUCTION. Having drawn PN perpendicular to BC in I, to meet AK parallel to BC in K, bisect PK in O, from which point on OK set off OG such, that the rectangle under OG and PG may be equal to the given one PI \cdot PO; from G, parallel to BC, draw GD meeting AC in D; then, if DF parallel to AB meet BC in F, and PD be drawn cutting BC in E, the triangle EDF will evidently be the maximum required.

XXIX. QUESTION 299, *answered by Mr. Wallace, Royal Military College.*

ANALYSIS. Suppose the lines drawn as required. From B, (fig. 673, pl. 32.) one of the given points in the circumference

of the given circle, draw BY to one of the given points in the lines given by position; let BY cut the circle again in C ; join AC , and take $AD = BY$; the points D, C , are evidently both given in position; through these points and the given point Y describe a circle cutting the given line YH in F , join FD cutting AE in K , the point F and therefore the line FK are also given in position. The triangles BHY, AKD , are in all respects equal, for $FD \perp CY$ being a quadrilateral in a circle the outward angle HYB is equal to the inward and opposite angle FDC , or to ADK which is vertical to FDC ; the angles CBE, CAE , that is YBH, DAK are also equal, for they are in the same segment of the given circle; therefore the triangles YBH, DAK are equiangular, but they have the sides BY, AK (which are opposite to equal angles in each) equal by construction, therefore the remaining sides of the one triangle are equal to those of the other, so that DK is equal to YH : hence the sum or difference of the squares of XG, YH is equal to the sum or difference of the squares of XG, DK ; thus the proposed question is reduced to the following. Let DK, XG be two straight lines given by position and D, X given points in those lines, also let A be a given point without them: It is required to draw a line through A to cut them in K and G so that $DK^2 - XG^2$ may be a given space; or so that $DK^2 - XG^2$ may be equal to a given space. We proceed to consider the question under its new form.

Draw AL parallel to GX cutting KD in L , and draw AM parallel to KD , cutting GX in M , the lines AL, AM are evidently given in magnitude. The triangles KLA, AMG are similar, therefore $KL : LA :: AM : MG$, hence $KL \times MG = AL \times AM =$ a given space. Draw GO perpendicular to GX , and equal to KL , then the given rectangle $KL \times GM$ becomes $GO \times GM$, and since the point M , also the line MG are both given by position, the locus of O is a given right angled hyperbola having MG for one of its asymptotes; the other will pass through M at right angles to MG . Draw XP perpendicular to XG and equal to DL , thus P will be a given point; draw PQ parallel to XG , meeting OG in Q , then the line PQ is given by position; and since by construction $OG = KL$, also $GQ = PX = DL$, we have $OQ = DK$, now $PQ = GX$, therefore $DK^2 \pm XG^2 = OQ^2 \pm QP^2$.

Now if $YH^2 + GX^2 = DK^2 + XG^2$ be given, then $OQ^2 + QP^2 = OP^2$ is given, therefore the point O is in the circumference of a circle whose centre is a given point P , and radius a given line PO ; but the same point is also in a given hyperbola as has been already shewn, therefore the point O is determined, and hence

hence the position of the line OG and the line GAE, as was required. If again $YH^2 - GX^2 = DK^2 - GX^2$ be given, then $QO^2 - QP^2$ is given so that in this case the Locus of O is another right angled hyperbola whose centre is P, and conjugate axis in PQ, and therefore the problem may be resolved by the intersection of two hyperbolas.

In general, let the relation between XG and YH be expressed by any equation whatever involving these indeterminate quantities and known magnitudes only, the same equation will express the nature of a curve which is the locus of the point O. Thus we have shewn how the general problem may be resolved, not only in the two cases mentioned in the question, but in innumerable others which might be proposed. If for example we had $XG + YH =$ a given line then also $PQ + QO =$ a given line, or since PX, XM are given, $MG + GO =$ a given line, but here we may dispense with the hyperbola, for we have only to determine two lines MG, GO whose sum and rectangle are both given; and similar simplifications will apply to other cases. As to the construction it follows so obviously from the analysis that for the sake of brevity it may be omitted.

XXX. OR PRIZE QUESTION 300, answered by Limenus, Bruton, Somerset.

LEMMA. If the side AB (fig. 659, pl. 32.) of any triangle be divided in P in the duplicate ratio of AC : BC the other two sides, and perpendiculars are let fall from P on these sides, the sum of the squares of those perpendiculars, $PM^2 + PN^2$, is the least possible.

Triangles of the same altitude being as their bases

$$\Delta APC : \Delta PCB :: AC \cdot PM : BC \cdot PN :: AP : PB \\ :: (\text{by const.}) AC^2 : BC^2; \text{ whence}$$

$$PM : PN :: AC : BC, \text{ and } \frac{PM^2}{AP} = \frac{PN^2}{BP}.$$

Let P be any point between P and B, and since

$$AB + \frac{Pb^2}{AP} + \frac{Pb^2}{BP} = \left\{ \begin{array}{l} AP + 2Pb + \frac{Pb^2}{AP} \\ + BP - 2Pb + \frac{Pb^2}{BP} \end{array} \right\} = \frac{Ab^2}{AP} + \frac{Bb^2}{BP}$$

T 3

AB

AB is less than $\frac{Ap^a}{AP} + \frac{Bp^a}{BP}$;

but because of the similar triangles

APM, Ap_m , and BPN, Bp_n ,

$\frac{Ap^a}{AP^a} = \frac{pm^a}{PM^a}$, and $\frac{Bp^a}{BP^a} = \frac{pn^a}{PN^a}$, therefore

AB = AP + BP is also less than $AP \times \frac{pm^a}{PM^a} + BP \times \frac{pn^a}{PN^a}$,

and multiplying the whole by $\frac{PM^a}{AP}$ and its equal $\frac{PN^a}{BP}$,

$PM^a + PN^a$ is less than $pm^a + pn^a$.

In like manner the same thing may be proved when p is between A and P.

Fig. 660, pl. 32. Draw $ab \parallel$ to the base AB at any distance therefrom, which divide in R in the duplicate ratio of the sides, and join CR meeting ab in Q; then since $aQ : bQ :: (AR : BR :: AC^a : BC^a ::) Ca^a : Cb^a$, the sum of the squares of QM, QN will be less than of those drawn from any other point in ab , by the preceding lemma.

Now divide either of the sides AC in S in the duplicate ratio of the remaining sides of the triangle, and join BS meeting CR in Q, and join AQ to meet BC in T; then, because (by Simpson's Geom. IV. 23.) BT : TC is in the compound ratio of BR : RA, and AS : SC, it is likewise in the duplicate ratio of BA : AC. Therefore the sums of the squares of the perpendiculars QL, QM, and QN, QL, QN are respectively less than those from any other point in lines drawn through Q \parallel to BC, AC. Whence the point Q being so determined, that the sum of the squares of every two of the three perpendiculars QL, QM, QN drawn from thence to three sides is the least, while the third remains constant, we may assume Q from whence the squares of those perpendiculars make together the least sum.

Moreover the $\triangle ABC$ being equal to the three AQB , BQC , AQC , its double is = $QL \cdot AB + QM \cdot AC + QN \cdot BC$.

But $QM : QN ::$ (by the demon. to the lem.) $Ca^a : Cb^a :: CA : CB$, therefore the perpendiculars from Q are as the sides on which they stand, and

$QM \cdot AB$

$QM \cdot AB = QL \cdot AC$, and $QN \cdot AB = QL \cdot BC$, whence
 $AB \times \frac{1}{2} \Delta ABC = QL \cdot AB^2 + QM \times AB \times AC + QN \cdot AB \cdot BC$
 $= QL \times (AB^2 + AC^2 + BC^2)$, and
 $QL \times \frac{1}{2} \Delta ABC = AB \cdot QL^2 + AC \times QL \times QM + BC \cdot QL \cdot QN$
 $= AB \times (QL^2 + QM^2 + QN^2)$; wherefore
 $AB : QL :: AB^2 + BC^2 + AC^2 : \frac{1}{2} \Delta ABC :: \frac{1}{2} \Delta ABC : QL^2 + QM^2 + QN^2$.

Q. E. D.

The same, by Mr. I. T. M'Doneld.

LEMMA. Let there be any number of known quantities AB , AC , AD , &c. (fig. 682, pl. 33.) and as many variable quantities Ax , Ay , Az , &c. such that the sum of their rectangles, $AB \cdot Ax + AC \cdot Ay + AD \cdot Az$, shall be equal to a given space; then, I say, the sum of the squares of the unknown quantities, $Ax^2 + Ay^2 + Az^2$, &c. will be a minimum, when the respective factors have one common ratio to each other, viz. $AB : Ax = AC : Ay = AD : Az$, &c.

Suppose $AD : Az$ to be a constant magnitude; and, if the sum of the squares of Ax and Ay be not a min. take Ax' less than Ax , and Ay' greater than Ay in an inverse ratio, that is, $Ax : Ay :: y'y : xx'$, or rect. $Ax \cdot xx' = Ay \cdot y'y$.

Now $Ax^2 - Ax'^2 = Ax'x + Ax'x$, and $Ay'^2 - Ay^2 = Ay'y + Ay'y$; the diff. of these two quantities is theref. $Ax'x > Ay'y$ but rect. Ay/y exceeds rect. $Ax'x$ in as much as the ratio of Ay' to Ax' exceeds that of $x'x$ to $y'y$; and theref. Ay'^2 exceeds Ay^2 more than Ax^2 exceeds Ax'^2 ; and vice versa if Ax' be taken greater than Ax , its square would exceed that of Ax more than Ay^2 would exceed Ay'^2 . Hence $Ax^2 + Ay^2$ is the least possible when $Ax : AB = Ay : AC$. It is easy to conceive that the proposition is equally true in *more* quantities than two.

This premised, the point Q may be determined as follows: find P (fig. 683, pl. 33.) the centre of gravity of the ΔABC , whence demit Pm , Pn , Po , perp. to the sides of the Δ , and find O the centre of a circle passing through the points m , n , o , through which draw PQ , making $OQ = OP$ and Q is the point required, as will appear in the following demonstration of the theorem.

DEMON. Demit the perps. Qp , Qq , Qr , and on the centre O with rad. OP or OQ describe a circle intersecting the perp. from P

P in a , b , and c . Then, the points m , n , o being equi-distant from O, the rectangles amP , Pnb , ocP , and consequently their equals $Qp.Pm$, $Qq.Pn$, $Qr.Po$ are equal to each other; and as Pm , Pn , Po are inversely as the sides on which they stand, Pm , Pn , Po will be directly as the sides, (according to the Lemma),

for $Qp : Qq = Pm : Pn = AB : BC$;

and $Qq : Qr = Po : Pn = BC : AC$:

$Qp^2 + Qq^2 + Qr^2$ is therefore a minimum.

Again rectangle $Qp.Pm = Qp^2$ — rectangle pQd ;

rectangle $Qq.Pn = Qq^2$ + rectangle nbP ,

and rectangle $Qr.Po = Qr^2$ — rectangle ocP ;

but as the Δ 's AQB and CQA exceed APB and CPA as much as CQB is less than CPB, so rectangles $pQd + ocP = nbP$, and therefore $Qp.Pm + Qq.Pn + Qr.Po = Qp^2 + Qq^2 + Qr^2$.

Now $(AB^2 + BC^2 + AC^2) \times (Qp.Pm + Qq.Pn + Qr.Po)$ and

$(AB \cdot Pm + BC \cdot Pn + AC \cdot Po) \times (AB \cdot Qp + BC \cdot Qq + AC \cdot Qr)$ when actually multiplied, will by proper substitution of equal rectangles, be found equal to each other. Hence $AB^2 + BC^2 + AC^2$: twice the area :: twice the area : $Qp^2 + Qq^2 + Qr^2$.

Q. E. D.

The same, by Tyro Philomatheticus.

LEMMA. If in any right line AB, (fig. 661, pl. 32.) a point C be taken, such, that $m \cdot AC^2 + n \cdot CB^2$ is the least possible, then AC is to CB as n to m ; m and n being given or constant.

DEMONSTRATION. For let D be any point in AB, then $m \cdot AD^2 + n \cdot DB^2 = m \cdot (AC + CD)^2 + n \cdot (CB - CD)^2 = m \cdot (AC^2 + 2AC \cdot CD + CD^2) + n \cdot (CB^2 - 2CB \cdot CD + CD^2)$,

or, since $AC : CB :: n : m$, $CB = \frac{m}{n} \cdot AC$,

$m \cdot AD^2 + n \cdot DB^2 = m \cdot (AC^2 + 2AC \cdot CD + CD^2) +$

$n \cdot (\frac{m^2}{n^2} \cdot AC^2 - \frac{m}{n} \cdot 2AC \cdot CD + CD^2)$, which is manifestly

greater than $m \cdot AC^2 + n \cdot CB^2$ ($\equiv m \cdot AC^2 + n \cdot \frac{m^2}{n^2} \cdot AC^2$) by

$\overline{m + n} \cdot CD^2$.

Let

Let ABC (fig. 662, pl. 32.) be the triangle, and QD , QE , QF the perpendiculars mentioned in the question, and CI perpendicular to AB , and suppose the point Q to be somewhere in the line GQH which is drawn parallel to AB ; then since QD (let it be what it will) is the same in every point of GQH , we now have to find QF and QE , such, that $QF^2 + QE^2$ shall be a minimum; the line GQH being parallel to AB , the angle $QGF = \text{angle } BAC$, and the angle $QHE = \text{angle } ABC$, and QFG and QFH are right angles, therefore by similar triangles

$$AC : CI :: QG : QF = \frac{CI}{AC} \cdot QG, \text{ and}$$

$$BC : CI :: QH : QE = \frac{CI}{BC} \cdot QH, \text{ whence}$$

$$\frac{CI}{AC} \cdot QG^2 + \frac{CI}{BC} \cdot QH^2 = QF^2 + QE^2 = \text{a minimum, and}$$

consequently by the Lemma ($\frac{CI}{AC}$ and $\frac{CI}{BC}$ being given)

$$QG : QH :: \frac{CI}{BC} : \frac{CI}{AC} :: AC : BC, \text{ therefore}$$

$$QF : QE (:: \frac{CI}{AC} \cdot QG : \frac{CI}{BC} \cdot QH) :: \frac{CI}{AC} \cdot AC : \frac{CI}{BC} \cdot BC :: AC : BC,$$

and by proceeding in a similar manner with QE and QD or QF and QD we shall get

$$QE : QD :: BC : BA, \text{ or } QF : QD :: AC : AB.$$

Hence the point Q may be found, by Prob. XXX. Simp. on Constr. of Geom. Probs. at the end of his Geom. the perpendiculars (when the sum of their squares is a minimum) being as the sides on which they fall.

Now twice the area of the triangle is
 $AB \times QD + BC \times QE + AC \times QF$, but

$$AB : BC :: QD : QE = \frac{BC}{AB} \cdot QD, \text{ and}$$

$$AB : AC :: QD : QF = \frac{AC}{AB} \cdot QD, \text{ whence}$$

twice

$$\text{twice the area} = AB \times QD + BC \times \frac{BC}{AB} \cdot QD + AC \times \frac{AC}{AB} \cdot QD$$

$$= \frac{QD}{AB} \times (AB^2 + BC^2 + AC^2),$$

and the sum of the squares of the perpendiculars

$$= QD^2 + \frac{BC^2}{AB^2} \cdot QD^2 + \frac{AC^2}{AB^2} \cdot QD^2$$

$$= \frac{QD^2}{AB^2} \times AB^2 + BC^2 + AC^2; \text{ hence}$$

$$AB^2 + BC^2 + AC^2 : \frac{QD}{AB} (AB^2 + BC^2 + AC^2)$$

$$\therefore \frac{QD}{AB} \times (AB^2 + BC^2 + AC^2) : \frac{QD^2}{AB^2} \times (AB^2 + BC^2 + AC^2).$$

Q. E. D.

The same, by Mr. W. Smith.

LEMMA. Fig. 663, 664, pl. 32. If the base AB of a Δ be divided in Q so that $AQ : QB :: AC^2 : BC^2$ the sum of the squares of the \perp s demitted from Q on the sides will be less than if Q were taken any where else in the base.

DEMONSTRATION. Draw QL so that the $\angle ALQ = \angle ABC$; and demit the \perp s QR, QP then by construction $AQ : QB :: AQ^2 : AQ \cdot QB$ (by hypothesis) :: $AC^2 : CB^2$ (by sim. Δ s ACB, AQL) :: $AQ^2 : QL^2$; therefore $AQ \cdot QB = QL^2$. Now if QT be always erected \perp to AB and equal to QL, the locus of T will be a right line given in position, as AT but by reason of the equal \angle s L and B in the right angled Δ s QRL, QBP, $QR^2 + QP^2$ will be a minimum when $QL^2 + QB^2$ is such, that is, when $(QT^2 + QB^2) BT^2$ or BT is such, and it has been proved above that $AQ \cdot QB = (QL^2) QT^2$; therefore the $\angle ATB$ is right and BT or BT^2 or $BQ^2 + QL^2$ or $QP^2 + QR^2$ is a minimum.

Q. E. D.

Hence it appears that with respect to the Δ ACB the locus of the point Q mentioned in the question is the right line CQ and the

the point itself from which the \perp s demitted on the sides have the sum of their squares, a minimum must be a point q such that drawing $MqN \parallel AB$, $MN \cdot Nq$ may be $= BN \cdot NC$, for demitting the \perp s qI , qE , qF and drawing $qO \parallel QL$ and $qS \parallel CB$ the Δ s qOF , qNE , qSI are all similar, therefore $qO^2 + qN^2 + qS^2$ is a minimum, that is to say $Nq \cdot NM + NB^2$ is a minimum; now it appears (since $Nq \cdot NM : NC^2$ in a given ratio) that if NG be erected \perp to NC and such that $NG^2 = NM \cdot Nq$ the locus of the point G will be a right line CG given in position and GB^2 will always be equal to $BN^2 + NG^2 = BN^2 + NM \cdot Nq = BN^2 + Nq^2 + qO^2 = qS^2 + qN^2 + qO^2$, therefore $qS^2 + qN^2 + qO^2$, and consequently $qI^2 + qL^2 + qE^2$ will be a minimum when BG is a minimum, that is when BG is \perp to CG or as above said when $BN \cdot NC = (NG^2) = NM \cdot Nq$.—Hence the following

DEMONSTRATION OF THE THEOREM.

Produce AB to Y so that $AB \cdot AY$ may be $=$ to $AB^2 + BC^2 + CA^2$, divide AB in g so that $Aq : qB :: AC^2 : CB^2$, join Cq and demit the \perp CD ; draw $MQNG \parallel AB$ so that $MN \cdot NQ = BN \cdot NC$, draw Bd , Bq' , $Ba \parallel CD$, Cq , CA respectively, join XY meeting BD in g and draw $ngQ'm \parallel ba$. Then from the construction it is evident that $AB \cdot AY = AC^2 + CB^2$ and also (since $Aq : qB :: AC^2 : BC^2$) that $Aq \cdot BY = AC^2$ and $Bq \cdot BY = BC^2$; now $YB : dX :: Bg : gd :: Bn : nC :: Bn^2 : Bn \cdot nC :: YB \cdot Bq : AB (dX) \cdot Bq :: BC^2 : AC \cdot Cq :: Bn^2 : mn \cdot nq$ that is $Bn^2 : Bn \cdot nC :: Bn^2 : mn \cdot nq$; whence $Bn \cdot nC = mn \cdot nq$; therefore $ag = DG$. But $AY \cdot AB : AX \cdot AB :: dX : (dg \cdot AX) DG \cdot DC$, that is $AC^2 + CB^2 + BA^2 : \text{twice the area} :: \text{twice the area} : \text{the sum of the squares of the } \perp \text{s demitted from } Q$, for per the Lemma $qO^2 + qN^2 + qS^2 : qF^2 + qE^2 + qL^2 :: qS^2 : qL^2 :: BN^2 : DG^2 :: BN \cdot BC : DG \cdot DC (dg \cdot AX)$; but $BN \cdot BC = qO^2 + qN^2 + qS^2$, therefore $DG \cdot DC = qL^2 + qE^2 + qI^2$.

N. B. In this solution reference must be had to both figures all along.

The same, by Mr. John Whitley.

Let ACB (fig. 697, pl. 33.) be any plane Δ , and P a given point within it from which perpendiculars are drawn to the sides. Then since the sum of the squares of those perpendiculars must be

a minimum, any two of them may be varied independent of the third; therefore through the point P, draw GH parallel to BC meeting AC, and AB in H and G, and join AP, BP, CP, and GC. It will readily appear, that whenever the point P falls in GH, the sum of the Δ s APC, APB will always be equal to the constant Δ ACG, and consequently if one of these Δ s, as APB, be increased by the small rectangle $AB \times m$, the other, APC, will have decreased by the same rectangle $AB \times m = AC \times n$; that is, if the perpendicular PD, be increased till it becomes equal to $PD + m$, the perpendicular PE will be decreased till it becomes equal to $PE - n$; and consequently $PD^* + PE^*$ will be ultimately equal to

$$(PD + m) \times PD + (PE - n) \times PE$$

$$\text{and therefore } PD \times m = PE \times n;$$

$$\text{and because } AB \times m = AC \times n, \text{ we have } PD \times AC = PE \times AB, \text{ or}$$

$$PD = \frac{PE \times AB}{AC}.$$

In the very same way it may be shewn that

$$PF = \frac{PE \times BC}{AC}.$$

Now draw CR perpendicular to AB; then

$$\begin{aligned} CR \times AB &= PD \times AB + PF \times BC + PE \times AC \\ &= \frac{PE \times AB^*}{AC} + \frac{PE \times BC^*}{AC} + PE \times AC; \end{aligned}$$

$$\text{consequently } PE = \frac{AC \times CR \times AB}{AB^* + BC^* + AC^*}; \text{ wherefore}$$

$$PF = \frac{BC \times CR \times AB}{AB^* + BC^* + AC^*};$$

$$\text{and } PD = \frac{AB \times CR \times AB}{AB^* + BC^* + AC^*}.$$

$$\text{Hence } PE^* + PF^* + PD^* = \frac{CR^* \times AB^*}{AB^* + BC^* + AC^*}; \text{ or}$$

$$\begin{aligned} AB^* + BC^* + AC^* : CR \cdot AB &:: CR \cdot AB : PE^* + PF^* + PD^*; \\ \text{that is, } AB^* + BC^* + AC^* : 2\Delta ACB &:: 2\Delta ACB : PE^* + PF^* + PD^*. \end{aligned}$$

Q. E. D.

The

The same, by Mr. James Cunliffe.

Fig. 698, pl. 33. Let Q be the point in the triangle ABC from whence perpendiculars being drawn to the sides, the sum of their squares will be the least possible. Through Q let the right lines DE, FG, and HI be drawn parallel to the sides AB, BC, and AC respectively.

Put $AB = a$, $BC = b$, $AC = c$, and $HF = x$, and let Δ denote the area of the $\triangle ABC$. Then $\frac{2\Delta}{AB}$ will express the

length of a perpendicular from the $\angle C$ upon AB; and, by the property of the point Q, as demonstrated in the Tracts and Selections, in Art. 28 of Playfair's Paper on the Origin and investigation of Porisms.

$AB^2 : AC^2 :: FQ : QG :: HF : DQ = AH$, that is,

$$AH = \frac{AC^2 \times HF}{AB^2} = \frac{c^2 x}{a^2}; \text{ and for the same reason}$$

$$AB^2 : BC^2 :: HF : QE = FB = \frac{BC^2 \times HF}{AB^2} = \frac{b^2 x}{a^2};$$

$$\text{therefore } AH + HF + FB = \frac{c^2 x}{a^2} + x + \frac{b^2 x}{a^2} = AB = a;$$

Whence $x = \frac{a^2}{a^2 + b^2 + c^2}$. Again per similar Δ s

$$AB : HF :: \frac{2\Delta}{AB} : \frac{2\Delta \times HF}{AB^2} = \frac{2\Delta x}{a^2} = \frac{2\Delta a}{a^2 + b^2 + c^2} =$$

the length of a perpendicular from Q upon AB. And in the same way we shall find that

$\frac{2\Delta b}{a^2 + b^2 + c^2}$ and $\frac{2\Delta c}{a^2 + b^2 + c^2}$ express the lengths of perpendiculars from Q, upon BC and AC respectively.

And the sum of the squares of the said perpendiculars is

$$\frac{4\Delta^2 \times (a^2 + b^2 + c^2)}{(a^2 + b^2 + c^2)^2} = \frac{4\Delta^2}{a^2 + b^2 + c^2} \text{ from whence it is}$$

very obvious that twice the area of the $\triangle ABC$ is a mean proportional

portional between the sum of the squares of the perpendiculars from Q, and the sum of the squares of the sides of the triangle.

The same, answered by Asinus,

LEMMA. *Problem.* In a plain triangle ACB (fig. 662, pl. 32.) it is required to find a point Q in one side, such that the sum of the n th powers of QF and QE, drawn perpendicular to the other two sides, may be a minimum.

Put $QG = x$, $GH = a$; then $QF = x \times \sin. G$, and $QE = (a - x) \times \sin. H$; and the quantity to be a minimum is $x^n \times \sin. {}^n G + (a - x)^n \times \sin. {}^n H$; putting the fluxion $= 0$ we easily get $x^{n-1} \times \sin. {}^n G = (a - x)^{n-1} \times \sin. {}^n H$; that is $QG^{n-1} \times \sin. {}^n G = QH^{n-1} \times \sin. {}^n H$. Whence $QG^{n-1} : QH^{n-1} :: \sin. {}^n H : \sin. {}^n G :: GC^n : CH^n$. Therefore the point Q is found by dividing GH in a certain given proportion.

Cor. The $(n-1)$ th powers of the perpendiculars QF and QE are as the sides of the triangle on which they fall.

For, since $x \sin. G = QF$ and $(a - x) \sin. H = QE$, therefore, because $x^n \times \sin. {}^n G = (a - x)^n \times \sin. {}^n H$, $QF^{n-1} \times \sin. G = QE^{n-1} \times \sin. H$. Consequently $QF^{n-1} : QE^{n-1} :: \sin. H : \sin. G :: GC : CH$.

Demonstration of the Prize Question.

Let ACB be the triangle, and Q the point such that the sum of the squares of QF, QE, and QD is a minimum; and through Q draw GH parallel to one side as AB. Then, because all the perpendiculars drawn from GH to AB are equal, the sum of the squares of QF and QE must be less than the sum of the squares of perpendiculars drawn from any other point in GH to GC and CH. Therefore (Cor. to Lem. putting $n = 2$) $QF : QE :: GC : CH :: AC : CB$.

But what has been demonstrated of QF, QE, and the sides AC and CB may in like manner be demonstrated of QF, QD and AC, AB, therefore we have these two proportions.

$$QF : QE :: AC : CB$$

$$QF : QD :: AC : AB.$$

Now,

Now, from the proportions just found, we readily derive these two (E. 1. 6)

$$QF^* : QE^* :: AC \times QF : BC \times QE$$

$$QF^* : QD^* :: AC \times QF : AB \times QD$$

whence (E. 12. 5)

$$\left. \begin{array}{l} \{ QF^* : (QF^* + QE^* + QD^*) :: AC \times QF : (AC \times QF + BC \times QE) \\ \{ + AB \times QD =) \triangle ACB. \end{array} \right\}$$

Again, from the same two proportions, the two following are in like manner derived, viz.

$$QF \times AC : QE \times BC :: AC^* : CB^*$$

$$QF \times AC : QD \times AB :: AC^* : AB^*$$

whence (E. 12. 5)

$$\left. \begin{array}{l} \{ QF \times AC : (QF \times AC + QE \times BC + QD \times AB =) \triangle ACB :: \\ \{ AC^* : (AC^* + BC^* + AB^*) \end{array} \right\}$$

But, if the two proportions that have now been demonstrated be taken alternately, the two first ratios will evidently be equal; therefore also the two latter ratios will be equal; that is

$$QF^* + QE^* + QD^* : \triangle ACB :: \triangle ACB : AC^* + AB^* + BC^*.$$

Q. E. D.

=====

The Medal for solving the Mathematical Prize Question is decided in favour of Mr. I. T. M'DONELD, who will please to send for it to Mr. GLENDINNING'S.

ARTICLE XXI.

Answers to the Mathematical Questions proposed in
ARTICLE XV. No. XIII.

I. QUESTION 301, answered by Mr. Tho. Boole.

The side of the octagon being 10 chains its area was 48.28427 acres, and annual rent £96.56854. Therefore, by Dr. Hutton's Theorems for Annuities in arrear, (at page 260, Vol. I. of the Course.)

$$\frac{1.05^5 - 1}{1.05 - 1} \times 96.56854 = £20216.8s. 7\frac{1}{2}d. \text{ the sum required.}$$

Ingenious answers were also given by Messrs. Amos, Collins, Cunliffe, Exton, Francis, Heward, Morley, I. Smith, Squire, Thompson, Tyro Philomatheticus, and Whitley.

II. QUESTION 320, answered by Masters Wm. Amos and Wm. Exton, at Frieston School, near Boston.

Put a = axis, s = surface, S = solidity, and $p = 3.141592$ &c. Then

First, when $s = S$, we have $pa^2 = \frac{1}{6}pa^3$, or $a = 6$;

Secondly, when $a = S$, we have $a = \frac{1}{6}pa^3$, or $s = pa^2 = 6$;
and

Thirdly, when $a = s$, we have $a = pa^2$, or $a = \frac{1}{p}$, and

$$\text{therefore, } S = \frac{1}{6}pa^3 = \frac{1}{6p^2} = .016885.$$

That is, when the superficies and solidity of a globe are equal the axis is 6; when the axis and solidity are equal the superficies is 6; and when the axis and superficies are equal, the solidity is equal

equal to unity divided by 6 times the square of the circumference of a circle whose diameter is unity or 1.

Ingenious answers were also given by Messrs. Boole, Collins, Cunliffe, Francis, Hearing, Morley, Thompson, Tyro Philomatheticus, and Whitley.

III. QUESTION 303, answered by Mr. Pishey Thompson, of Friston School, near Boston.

First $70\frac{1}{2}$, the cubic inches in an ale quart, divided by $(4^{\circ} \times 7854) = 5.6102 = AC$, (fig. 696, pl. 33.) Since ad is perpend. to CaC ; by Euc. 13, VI. $Ca \times ac = (ad)^2$, whence $Ca = .268$. Let ae be drawn parallel to CA ; then will $eb = AB - ae - bB = AB - 2Ac = AB - 2Ca = 3.464$; finally $(ab)^2 = (ae)^2 + (eb)^2 = (CA)^2 + (eb)^2 = 43.494544$; or $ab = 6.595$ inches nearly the length of the brass plate.

The same, by Mr. Thos. Morley.

First $\frac{70.5}{4^{\circ} \times 7854} = 5.6102$ the depth of the quart. Then

$2\sqrt{(2^{\circ} - 1^{\circ})} = 3.46414$, the distance of the lower end of the plate from a point on the bottom directly under the upper end; therefore $\sqrt{(5.6102^2 + 3.4641^2)} = 6.5935$ inches the length of the plate required.

Other ingenious solutions were given by Messrs. Collins, Cunliffe, Francis, Hearing, I. Smith, Squire, Tyro Philomatheticus, and Whitley.

IV. QUESTION 304, answered by Mr. Thos. Boole.

Fig. 686, pl. 33. Let AB and CD be the poles, EF the chord, G the point in which the poles meet, and GH the perpendicular on the ground, then will ILK be the position of the chord when the poles meet;

U 3

Now

Now $IL = LK = HD = DK = 5$ yards, and $\sqrt{(5^2 + 3^2)} = \sqrt{34} = DL$;
 and $DL : \text{radius} :: HL : \text{sin} \angle HDL = 30^\circ 57' 49''$,
 also KL and KD being equal we have
 $DK : \text{radius} :: \frac{1}{2}DL : \text{cosine} \angle LDK = 54^\circ 19' 53''$,
 and $HDL + LDK = HDG = 85^\circ 17' 42''$,
 and $\text{cosine} \angle HDG : HD : \text{radius} :: DG = 60.9567$ yards, the
 length of the poles, as required.

The same answered, by Mr. Tho. Squire, Baldock.

Let AB, CD represent the poles, EF the rope, e the middle point thereof, or the first position of the weight.

Let L be the position of the weight when the poles meet at G ,
 bisect BD in H and join HG, DL , and draw LX perpend. to
 DL meeting DG in X , also draw VX parallel and PX perpend.
 to DH .

Then because $LK = eF = \frac{1}{2}BD = 5$ and $DF = DK = 5$,
 we have $LK = DK = KX = 5$ (because $\angle DLX$ is a right one);
 therefore $DX = 10$, and since $Le = 2$, $HL = 2$; therefore
 $DL = \sqrt{(HL^2 + DH^2)} = \sqrt{(3^2 + 5^2)} = \sqrt{34}$, and
 $LX = \sqrt{(DX^2 - DL^2)} = \sqrt{66}$. But by sim. Δ s,

$$DL (= \sqrt{34}) : HL (= 3) :: LX (= \sqrt{66}) : VX = 3\sqrt{\frac{66}{34}} = 4.179783;$$

also $DP = DH - VX (= 8.20217) : DX (= 10) : DH (= 5) : BD$
 also $DP = DH - VX : DX :: DH : DG = 60.95944$ yards the
 length of the poles.

The same, by Mr. William Francis, Taplow, near Maidenhead.

Here $\sqrt{(5^2 - 2^2)} = 1e$, and $1e \times 2 = IK$;
 also $\frac{1}{2}(BD - IK) = Bi$; and $Bi : BI :: bH : EG = DG = 60.96$ yards nearly, the answer.

This Question was also answered by Messrs. Collins, Cunliffe, Heward, Morley, Tyro Philomatheticus, and Whitley.

V. QUESTION 305, answered by Mr. John Collins, Kensington.

Let p = the product of the required numbers, then the sum of the n th powers will be expressed by

$$s^n = n (s^{n-2}) p + n \cdot \frac{n-3}{2} (s^{n-4}) p^2 + n \cdot \frac{n-4}{2} \cdot \frac{n-5}{3} (s^{n-6}) p^3 + n \cdot \frac{n-5}{2} \cdot \frac{n-6}{3} \cdot \frac{n-7}{4} (s^{n-8}) p^4 + \text{&c. taking } n = 9 \text{ we have}$$

$$512 - 1152p + 864p^2 - 240p^3 + 18p^4 = 32, \text{ or}$$

$$p^4 - \frac{40}{3} p^3 + 48p^2 - 64p + \frac{80}{3} = 0;$$

and this equation resolved into its factors, becomes

$$(p-2) \times (p-2) \times (p^2 - \frac{28}{3} p + \frac{20}{3}) = 0, \text{ and conseq.}$$

$$p^2 - \frac{28}{3} p + \frac{20}{3} = 0; \text{ a quadratic, one root of which is}$$

$$\frac{14 - \sqrt{34}}{3} = p. \text{ Now from the square of } (x+y) \text{ take } 4p;$$

and extracting the square root we have $x-y = \sqrt{(s-4p)}$.

$$\text{Therefore } x = \frac{s + \sqrt{(s^2 - 4p)}}{2} \text{ and } y = \frac{s - \sqrt{(s^2 - 4p)}}{2}.$$

$$\text{Whence } x = 1.4697175 \text{ and } y = .5302824.$$

Solutions to this question were also received from Messrs. Morley, and Whitley.

VI. QUESTION 306, answered by Mr. J. H. Hearding.

It is well known that a column of water whose height is 33 feet, is equal in weight to a column of air of the same base, and whose altitude is equal to that of the atmosphere above the earth's surface. It has also been found by divers experiments, that a body of water is to a body of air of an equal bulk as 850 to 1. If any number

number of altitudes of the atmosphere be taken in an increasing arithmetical progression, the respective densities of the air, at those altitudes, will form a decreasing geometrical progression; or, in other words, the densities of the air at the earth's surface B , and the heights BD , BF (see fig: 685, pl. 33) are to one another as the ordinates AB , CD , EF of the logarithmic curve ACE , whose asymptote is BDF . This is demonstrated by Dr. Halley, in the Philosophical Transactions, No. 181; it has also been very clearly proved by Dr. Gregory, in his valuable Treatise of Astronomy, Prop. 3, Book V. To apply what is here premised to the solution of the proposed question; assume $AB = 33$ feet, the height of a column of water; $BD = 850$, the altitude of a column of the atmosphere of equal weight with a column of water of 1 foot high; $CD = 32$ the density of the air at the height of 850 feet; $BF = 30$ miles $= 158400$ feet, the given altitude, and $EF =$ the density of the air at that height; then, since in the present case, AB is supposed to be equal 1, CD will be represented

by $\frac{32}{33}$; and,

as $850 (= BD) : 158400 (= BF)$ or
 $as 17 : 3168 :: \log. (AB \div DC) : \log. (AB \div EF) = 2.4904021$,
consequently $\log. EF = - 3.5095979$, and $EF = 0.0032329$,
the density of the air at the height of 30 miles when the density at the surface is = 1; let this = d , and put the capacity of the barrel and receiver together = 11 = c , that of the receiver alone = 9 = r , and the number of strokes of the piston, necessary to rarify the air to the given density d , = x ; then, by Hutton's Course Vol. II. page 329,

x is $= \frac{\log. d}{\log. r - \log. c} = \frac{- 2.4904021}{- 0.0871504} = 28.576$ turns of
the piston.

The same, by Mr. John Smith, Alton Park.

First, $\frac{30 \times 5280}{63551} = 2.4924863$ the logarithm of the rarity of the air at the altitude of 30 miles, when the temperature is 55° .

Then

Then $\frac{2.4924863}{\log. (9+2) - \log. (9)}$ = 28.6, nearly the number of strokes required.

See Dr. Hutton's Course of Mathematics, Vol. II. art. 329 and 341.

Ingenious solutions were also given by Messrs. Collins, Cunliffe, Thompson, and Tyro Philomatheticus.

VII. QUESTION 307, answered by Mr. Francis, the Proposer.

Draw the equilateral triangle FBC. (fig. 687, pl. 33.) On FC take FG = 12, and draw GH || to BC. From the centres G and H, with radii 8 and 9 describe arcs intersecting in I; and draw GI. Then if $\angle FCD$ be made = $\angle FIG$, the line CD will meet FI produced in the required point D.

For since the \angle s FCD, FIG are equal and GFI common to both the \triangle s CDF, FIG, the other \angle s must also be equal and the \triangle s similar. If HI be drawn it may be proved in the same manner that the \triangle s FIH, FBD are similar.

Again, draw DK \perp and = to BD; bisect KC in L and produce LC to M, making LM = DL. From M, through D draw the line MA, on which demit \perp s from B and C, then will ABCEDA be the garden required. For if KN be drawn \perp to AM the \triangle s ABD, DKN, will be similar and equal.

The \triangle EMC is also similar to the \triangle MKN; EM is evidently = DN and MN = DE.

Hence as EM : EC :: MN : KN consequently $\frac{1}{2} DE \cdot EC = \frac{1}{2} DN \cdot KN = \frac{1}{2} AB \cdot AD$.

W. W. R.

CALCULATION. In the \triangle HIG are given all the sides, whence the \angle s are = $41^\circ 25'$, $48^\circ 11'$, and $90^\circ 24'$. And the $\angle IGF = 108^\circ 11'$, the $\angle IHF = 101^\circ 25'$, $\angle IFG = 27^\circ 40'$, $\angle FIG = 44^\circ 10'$, $\angle IFH = 32^\circ 20'$, $\angle FIH = 46^\circ 15'$, and $IF = 16.368$. Therefore by sim. \triangle s, as $IF (= 16.368) : FC :: IG : DC = 29.32$ and :: $HI : BD = 32.985$. Now we have all the sides of $\triangle BCD$, consequently the \angle s $14^\circ 43'$, $16^\circ 36'$, and $148^\circ 41'$. Hence $\angle KDC = 58^\circ 41'$, $\angle DKC = 54^\circ 41'$, and $\angle DCK = 66^\circ 38'$.

Also the side KC = 39.697, the $\angle DLC = 82^\circ 8'$, $DL = LM$

$LM = 27.171$, whence $CM = 11.845$; also $\frac{1}{2} \angle DLC = \angle CEM = 41^\circ 4'$, whence $\angle LDM = \angle LMD = 48^\circ 56'$.

And therefore $EC = 8.9154$, and $ED = 27.9316$, and the area of the garden = 500 square yards.

VIII. QUESTION 308, answered by Mr. Wm. Marrat.

Put $.7854 = p$, and let the conjugate axe be denoted by x , then $1000 - x$ is the transverse axe, and $1000px - px^2$ is the area of the ellipse; also $\frac{1}{2}x + 500$ is its value in guineas: therefore

$$1000px - px^2 : \frac{1}{2}x + 500 :: 4840 : \frac{(\frac{1}{2}x + 500) \times 4840}{1000px - px^2} =$$

the value of one acre, which by the question is to be a minimum, or $\frac{\frac{1}{2}x + 500}{1000 - x}$, a minimum.

This put into fluxions and reduced, becomes $x^2 + 2000x = 1000$; whence $x = 1414.2135624$ the conjugate and $1000 - x = 585.7864376$ the transverse axis. Hence the area is 8846.11. 200. nearly.

The same, answered by Tyro Philomatheticus.

Let x = transverse, y = conjugate, $a = 1000$ yards, and $p = .7854$;

Then pxy = the content in square yards, and $\frac{1}{2}x + y$ = the value in guineas,

therefore $\frac{\frac{1}{2}x + y}{pxy}$ = the price per yard, which by the question

should be a minimum, or $\frac{x + 2y}{xy}$ = a minimum.

In fluxions $\frac{xy(x + 2y) - (x + 2y)(xy + xy)}{x^2y^2} = 0$,

or $x^2y + 2y^2x = 0$, but $x = -y$, hence $x^2 = 2y^2$, or

$x = y\sqrt{2}$, and therefore $x = a \times \frac{\sqrt{2}}{1+\sqrt{2}} = 585.79$, $y = a \times \frac{1}{1+\sqrt{2}} = 414.21$, and the area = 190569.456 yards.

IX. QUESTION 309, *answered by Mr. John Smith.*

The surface of a sphere or hemisphere is equal to the curve surface of its circumscribing cylinder, therefore $3.1416 \times 24 \times 40 = 3015.936$ feet = 335.104 yards, the surface of the balloon, or the quantity of silk required.

The solidity of a sphere being $\frac{4}{3}$ that of its circumscribing cylinder $78.54 \times 23^2 \times 32 = 14476.4928$ feet the capacity of the balloon.

$$\text{Hence } 14476.4928 \times \left(1\frac{2}{3} - \frac{1^2}{13}\right) = 16332.4534 \text{ ounces} =$$

9.11409 cwt, the weight with which it would ascend.

Now by Dr. Hutton's Mensuration, Prob. 2, page 269, 3rd. Edit. $(8800)^2 \div 3000 = 25813\frac{1}{3}$ the parameter, and, by Rule 1, Prob. 4. p. 271, *ibid*

$$\frac{25813\frac{1}{3}}{2} \times \left\{ \left\{ \sqrt{\left[\left(\frac{17600}{25813\frac{1}{3}} \right)^2 + 1 \right]} \right\} \times \frac{17600}{25813\frac{1}{3}} \right. \\ \left. + \text{hyp.log.} \left\{ \frac{17600}{25813\frac{1}{3}} + \sqrt{\left[\left(\frac{17600}{25813\frac{1}{3}} \right)^2 + 1 \right]} \right\} \right\} =$$

18954.6502 yards = 10.76968 miles, the length of the parabolic tract described by the Aeronaut.

It was also ingeniously answered by Messrs. Roole, Cunliffe, Francis, Hearing, Thompson, and Squire.

X. QUESTION 310, *answered by Ztrepmsg.*

An n should have been put within the first radical of the first and third expressions, and an m in that of the second expression. This being corrected, put x for the value and also in that part of the surd

surd where the expression recurs instead of continuing the surd, which will give an equation for x .

Thus in the first we have

$$x = \sqrt[n]{a} + \frac{b}{\sqrt[n]{a} + \text{&c.}} = \sqrt[n]{a} + \frac{b}{x}, \text{ therefore}$$

$$x^n = a + \frac{b}{x} \text{ and } x^{n+1} - ax = b.$$

In the second we have

$$x = \sqrt[m]{a} + \frac{b}{\sqrt[m]{c + \frac{d}{\sqrt[m]{a} + \text{&c.}}}} = \sqrt[m]{a} + \frac{b}{\sqrt[m]{c + \frac{d}{x}}}$$

$$= \sqrt[m]{a + \frac{bx^n}{\sqrt[m]{cx + d}}} = \sqrt[m]{\frac{a\sqrt[m]{cx + d} + bx^n}{\sqrt[m]{cx + d}}}.$$

$$\text{Therefore } x^m \times \sqrt[m]{cx + d} = a \times \sqrt[m]{cx + d} + bx^n.$$

And in the third we have

$$x = \sqrt{\frac{a}{b + \sqrt{\frac{a}{b + \text{&c.}}}}} = \sqrt{\frac{a}{b + x}}; \text{ therefore } x^{n+1} + bx^n = a$$

$\frac{1}{b + \text{&c.}}$

The chief use of these recurring surds or fractions is for solving equations which they sometimes do with advantage.

Thus if $x^{n+1} + bx^n = a$, be an equation in which b is greater than a we have

$$x = \sqrt{\frac{a}{b + x}} = \sqrt{\frac{a}{b + \sqrt{\frac{a}{b + \text{&c.}}}}} = \sqrt{\frac{a}{b + \sqrt{\frac{a}{b + \sqrt{\frac{a}{b + \text{&c.}}}}}}}$$

The same as above, which surd will continually approximate to the value of x .

XI. QUESTION 311, answered by Cap. Geo. Garry.

Let SCR (fig. 699, pl. 32.) represent a section of the given sphere passing through the centre O, and ABGI the inscribed cube; then it is manifest that AI the diagonal of the cube is a diameter of the sphere passing through the centre O. Hence to find AI or AG , let it be considered that

$AI^2 = AG^2 + GI^2 = AG^2 + Ga^2 + al^2 = 3AG^2$; therefore $AI = AG\sqrt{3}$, and $AG = AI \div \sqrt{3} = \frac{1}{3}AI\sqrt{3}$; that is, in the present case, the side of the inscribed cube is $4\sqrt{3} = 6.92820323$. Next to find the side cb , bd , or de , of the base of the octagonal pyramid (whose vertex will be V) let it be denoted by x ; and since abc is a right angled triangle having $ab = ac$,

it will be $ab : x :: 1 : \sqrt{2}$,

consequently $ab = x \div \sqrt{2} = \frac{1}{2}x\sqrt{2}$

and $ab + bd + dI = al$;

that is $x + 2 \times \frac{1}{2}x\sqrt{2} = x + x\sqrt{2} = al$;

hence $x = \frac{al}{1 + \sqrt{2}}$, and $x^2 = \frac{al^2}{3 + \sqrt{2}} = \frac{48}{3 + \sqrt{2}} =$ square

of a side of the octagonal base.

The solidity of the pyramid will therefore be

$$\frac{48}{3 + \sqrt{2}} \times \frac{4\sqrt{3}}{3} \times 4.8284271 = 91.8322 \text{ &c.}$$

It remains to find the solidity of the greatest circular spindle, inscribed in the space between As, and SCR. Here $CD = OC - OD = 2.53589838$, and $CE = 1.96794919$; from which, since CH is known, we easily find the area of the generating segment $RCSE = 6.38185136$.

Again $ER = \sqrt{(CE \cdot EH)} = \sqrt{\left\{ \frac{1}{2}DC \times (1 \frac{1}{2}DC + al) \right\}} = 3.6888611$.

Therefore (Dr. Hutton's Mensuration, page 215, Ed. II.)

$$\left\{ \frac{1}{2}ER^2 - (EO \times \text{area CER}) \right\} \times 4 \times 3.141593 = 20.5315 \text{ &c.}$$

solidity of the circular spindle RSCD. And consequently $91.8322 - 20.5315 = 71.3007$ the difference required.

The same, by Mr. John Smith.

By Dr. Hutton's Mensuration, page 186, 3d Edit. $4\sqrt{3} = 6.9282032$ the side of the cube. Then (ibid. pa. 85.) the area of an octagon whose side is 1 is 4.8284271 , which divided by 4, half the perimeter, gives 1.2071068 nearly for the perpendicular from the centre to the middle of one of its sides; and $6.9282032 \div 2 = 3.4641016$, the perpendicular from the centre of the base of the octagonal pyramid to the middle of one of its sides; whence by similar figures,

$(1.2071068)^2 : 4.8284271 :: (3.4641016)^2 : 39.764502$ the area of the base; then $39.764502 \times 6.9282032 \times \frac{1}{3} = 91.832183$ the solidity of the pyramid.

Next, $3.4641016 + \frac{6 - 3.4641016}{2} = 4.7320508$ the central distance of the spindle;

and $\sqrt{(6^2 - 4.7320508^2)} = 3.688861$ nearly, = half its length.

Then by Trigonometry,
 $6 : 3.688861 :: 1 \text{ (rad.)} : 61.48101 = \text{sin. } 37.938121 \text{ deg. theref.}$
 $\frac{37.938121 \times 0174533 \times 6}{2} - \frac{3.688861 \times 4.7320508}{2} =$

3.190678 , half the area of the generating segment.
Hence, by the Treatise above referred to, Prob. 21, pa. 158,

$\left\{ \frac{1}{2} \times (3.688861)^2 - (3.190678 \times 4.7320508) \right\} \times 4 \times$

$3.14159265 = 20.531552$ the solidity of the spindle.

Then $91.832183 - 20.531552 = 71.300631$ the difference required.

It was ingeniously answered by Messrs. Collis, Cunliffe, Hearding, and Whitley.

XII. QUESTION 312, answered by Mr. John Whitley.

Let FCB, ADF (fig. 674, pl. 88.) represent the garden, and suppose that CED is the longest walk which can possibly be made therein parallel to AB. Then by property of the semicircle

FE

$FE : CE :: CE : BE$ and by a property of the parabola

$DE : AB^2 :: FE : BF$; therefore

$DE^2 : CE^2 :: AB^2 : BE \times BF = CB^2$, or

$BC : AB :: CE : DE$; *componendo*

$BC + AB : AB :: DC : DE$.

Now AB is constant, and CD is a maximum; therefore $(BC + AB) \times DE$ is a maximum, which being fluxed and reduced gives

$$DE = \sqrt{AB^2 - \left\{ [\sqrt{(AB^2 + 8FB^2)} - AB] \times \frac{AB}{4FB} \right\}^2} =$$

27.548; hence $CE = 48.466$, and therefore $CD = 84$ yards nearly.

XIII. QUESTION 313, *answered by Mr. Cunliffe.*

ANALYSIS. Fig. 665, pl. 32. Draw the radius BO and from the centre O draw Om perpendicular to AC , and join Bm . Om bisects AC by Euc. III. 3. and

$a(Am)^2 + a(Bm)^2 = AB^2 + BC^2$, by Simpson's Geometry, Theor. 11, Book II. = a given magnitude by the question; therefore $(Am)^2 + (Bm)^2$ = a given magnitude.

Again $(Am)^2 + (Om)^2 = AO^2 = BO^2$ by Euc. I. 47, and taking the difference between this and the preceding gives

$(Bm)^2 - (Om)^2$ = a given magnitude, whence the locus of m in this case is known to be a right line perpendicular to BO . Now draw PO ; since the angle PmO is a right angle the locus of m in this case is known to be the circle whose diameter is PO ; therefore the intersection of these loci will be the point m , through which the line PAC must be drawn.

The same, by Mr. John Whitley.

ANALYSIS. Fig. 676, 677, pl. 33. Let O be the centre of the given circle ABC , join PB , PO , CO and bisect PB in R . Suppose that PAC is really drawn as required.

Let OS be drawn perpendicular to PAC , and join RS .

Then by known properties

X 2.

AC

$AC = CS$, $\frac{1}{2}AB^2 + \frac{1}{2}BC^2 = BS^2 + CS^2$, $OC^2 - OP^2 = CS^2 - PS^2$,
 wheref. $\frac{1}{2}AB^2 + \frac{1}{2}BC^2 + OP^2 - OC^2 = BS^2 + PS^2 = 2BR^2 + 2RS^2$,
 theref. $2RS^2 = \frac{1}{2}AB^2 + \frac{1}{2}BC^2 + OP^2 - OC^2 - 2BR^2$ = given space,
 which take equal to $2Q^2$; and we shall then have the following
 Construction.

Upon PO as a diameter describe the semicircle POS , to which
 from R , apply $RS = Q$; through S draw PAC meeting the cir-
 cle in A and C , and the thing will be done, as is manifest from
 the Analysis.

The same, by Mr. Swale, the Proposer.

ANALYSIS. Let PAC (fig. 678, pl. 33.) be supposed drawn
 as required. Join AB , BC ; bisect AC in G , and join BG , QG ,
 QA , QB , the centre of the circle being at Q .

Now $CB^2 + BA^2$ being given, its equal
 $\frac{1}{2}GB^2 + \frac{1}{2}GA^2$, or $\frac{1}{2}GB^2 + \frac{1}{2}QB^2 - \frac{1}{2}QG^2$ will be given;
 and QA or QB being a given line, it follows that,
 $\frac{1}{2}GB^2 - \frac{1}{2}QG^2$ or $GB^2 - QG^2 =$ a given space.

Demit upon BQ the perpendicular GE . Then.
 $GB^2 - QG^2 = BE^2 - QE^2$, or $BE^2 - QE^2 =$ a given space.
 Again, $BE^2 - QE^2 = (BE + QE) \times (BE - QE)$
 $= (BQ + \frac{1}{2}QE) \times BQ$
 $= BQ^2 + \frac{1}{2}QE \times QB$; consequently

$\frac{1}{2}QE \times QB =$ a given space, or QE a given line.

The point E is therefore given, and the lines BE , EG , given
 in position; that is, the point G is in a right line given in position;
 also, since PQ is given in length and position, and QG perpen-
 dicular to GP , it follows that the point G is in the circumference
 of the circle described upon the diameter PQ ; and therefore the
 point G is given.

Hence the following CONSTRUCTION.

Join the given points P , B with the centre Q , and on each side
 of the point B take, in BQ , BR , BR' each equal to the side
 of a square equal to the given space; in BQ , make $BQ : QR' =$
 $QR : QE$; draw EG perpendicular to EB , meeting a semicircle
 on PQ in G ; and draw, through P and G , the required line
 PAC .

XIV. QUESTION 314, answered by Mr. Cardiffe.

CONSTRUCTION. Fig. 679, pl. 33. Draw the radius CF perpendicular to AB and join FP . Upon CB take CR such that $2CP \times CR = FP^2$, and upon CR as a diameter describe a semicircle in which apply ST perpendicular to CR such that $4(ST)^2$ may be equal to the given sum of the squares of the perpendiculars.

Again, upon CP as a diameter describe another semicircle, and through O , the point where this latter semicircle cuts the line ST , draw the line required.

DEMONSTRATION. Draw CO which will be perpendicular to, and bisect DE by Euc. 31 and 3. III. also draw the perpendiculars Dm and En .

Because of the similar triangles CPO and COS ,
 $CP : CO :: CO : CS$, whence $CP \times CS = CO^2$.

Also by reason of the similar triangles PDm and PEn ,
 $PD^2 : PE^2 :: Dm^2 : En^2$, and by composition

$PD^2 + PE^2 : PE^2 :: Dm^2 + En^2 : En^2$, alternately

$PD^2 + PE^2 : Dm^2 + En^2 :: PE^2 : En^2$
 $\therefore CP^2 : CO^2 :: CP : CS$,

that is $CP : CS :: PD^2 + PE^2 : Dm^2 + En^2$.

Now $PD^2 + PE^2 = DE^2 - 2PD \times PE = DO^2 - 2PD \times PE$
 $= 4DC^2 - 4CO^2 - 2PD \times PE$,

and $PD \times PE = AP \times PR = DC^2 - CP^2$, wherefore

$PD^2 + PE^2 = 4DC^2 - 4CP^2 - 2 \times (DC^2 - CP^2)$.

$= 2DC^2 + 2CP^2 - 4CO^2$

$= 2DC^2 + 2CP^2 - 4CP \times CS$. And by confr.

$2CP \times CR = FP^2 = DC^2 + CP^2$, or

$4CP \times CR = 2DC^2 + 2CP^2$; whence

$PD^2 + PE^2 = 2DC^2 + 2CP^2 - 4CP \times CS$

$= 4CP \times CR - 4CP \times CS$

$= 4CP \times (CR - CS) = 4CP \times RS$. Theref.

$CP : CS :: PD^2 + PE^2 : Dm^2 + En^2 = 4CP \times RS : 4CS \times RS = 4ST^2$;

and from what is deduced above

$CP : CS :: PD^2 + PE^2 : Dm^2 + En^2$, wherefore

$Dm^2 + En^2 = 4ST^2$ the given space by the construction.

The following **THEOREM** may be gathered from the preceding solution.

In a given circle let the radius CF be drawn perpendicular to the diameter AB , and let the right line FP be drawn to any point P in AB ; also let CR be taken a third proportional to twice

CP and FP, and let circles be described upon CP and CR as diameters; then if at any point S between C and P, a right line SOT be drawn perpendicular to AB cutting the peripheries of the circles whose diameters are CP and CR, in O and T respectively; and if through P and O a right line be drawn to cut the given circle in D and E, and Dm, Em be drawn perpendicular to AB, then will $Dm^2 + Em^2 = 4(ST)^2$.

XV. QUESTION 315. *answered by Mr. Cunliffe.*

Fig. 680. pl. 33. Let a circle be described about the triangle, and bisect the base AB by the perpendicular MN meeting the circumference of the circumscribing circle below the base in N, and draw NC. With the centre N and radius NB describe another circle cutting NC in E, which will be the centre of the circle inscribed in the triangle ABC as is very well known; wherefore from E demit Ea perpendicular to AB and it will be the radius of the inscribed circle, and a the point of contact thereof with the base AB. Produce CN till it cuts the circumference of the circle whose centre is N in E, and draw Eb perpendicular to AB.

Then because $NE = NF$, Mb must be equal to Ma , and therefore $Bb = Aa$. Again by Euc. 35, III.

$LN \times LC = AL \times LB = LE \times LF$, whence

$LN : LF :: LE : LC$; and because of the \parallel s NM, Eb,

$LN : LF :: LM : Lb$, therefore

$LE : LC :: LM : Lb$, wherefore Cb and EM being drawn will be parallel to each other, from whence and what is before laid down the truth of the proposition will be manifest.

The same, by Mr. J. Collins, Kensington.

Produce ME to meet the perpendicular, let fall from the vertical angle upon the base, in P (fig. 681, pl. 33.)

It is evident that the triangles BMF and CDE are similar, and so are the triangles FME and CPE (DE being perpendicular to BC). Hence

$BF(EF) : FM :: CE : CP :: CE : DE$;

therefore $CP = DE = Eg$, and $EgCP$ is a parallelogram; wherefore

wherefore ME and bgC are parallel, and
 $bM : Ma :: Eg : Ea$, and therefore $bM = Ma$;

Wherefore $Bb + bM = Ma + aA$, that is, $BM = MA$.

Q. E. D.

The same, by Mr. John Dawes, Birmingham.

Fig. 637, pl. 31. Let fall the perpendiculars Ea , CK , and AM , continue ME till it meets CK in p . Now it is well known that $Cp = Ea$; and because $CpMl$ is a parallelogram $Cp = lM = Ea$; but $Ba = Aa$, and the triangles b/M , MEA are similar and equal, therefore M bisects ba , consequently it bisects AB , the base of the triangle.

Q. E. D.

The same, by Mr. Thomas Morley.

Fig. 681, pl. 93. Cb being joined will meet the circumference of the inscribed circle in the same point as aE produced to the circumference, as at g , by Prop. 58, Student. Therefore, because $aE = Eg$, and $EM \parallel bg$, $bM = Ma$; consequently BM is equal MA .

Q. E. D.

The same, by Mr. Whitley.

Fig. 673, pl. 92. Bisect AB in M , and join Ca , EM ; produce ME to meet Ca in P . Then because $AM = BM$, and Aa (or $AM + aM$) = Bb (or $BM + bM$), we have $aM = bM$. But it is now pretty well known that $CP = aP$ (see Gent. Diary, quest. 5, 1801). Wherefore the two sides Ca , ba of the triangle Cal are bisected in the points P and M respectively; therefore PEM is parallel to Cb ; that is, EM drawn parallel to Cb bisects the base AB in M .

This proposition was also demonstrated by Limenus, the Pre-poser.

XVI.

XVI. QUESTION 316, *answered by Astronomers.*

It is manifest that the duration of twilight is different at the same time of the year, in different climates of the earth; these differences are clearly stated in a few words in Art. 107, of O. Gregory's astronomy. Thus, "If a place be situated in a *parallel sphere*, or nearly so, the apparent motion of the sun being either quite or nearly parallel, he will be carried round for some months at a less depression than 18° , during which there will, of course, be no real night. In a *right sphere*, the twilight is shortest, because the sun rising and setting at right angles to the horizon, he is depressed 18° below the horizon in the shortest period. In any place in an *oblique sphere*, the nearer it is to one of the poles, the longer the twilight; and consequently, the nearer the equator, the shorter the twilight."

The twilight then being absolutely a minimum at the equator, at all times of the year, it is easy to find its duration; for at the time of the equinoxes it is nothing more than to find in what time 18° are passed over by the sun in a right sphere, the whole circle or 360° being passed over in 24 hours; thus, as $360^{\circ} : 18^{\circ} :: 24$ hours.

$$24 \text{ hours} : \frac{24 \times 18}{360} = \frac{6}{3} = 1 \text{h. } 12 \text{m. duration of shortest twilight}$$

at the equinoxes.

And at any other time of the year let P (fig. 666, pl. 32.) represent the pole, PH the horizon, being a secondary to the equator in a right sphere, H the sun's place, and HC = 18° , the distance from the horizon to the crepusculum circle. Then PH = 90° — sun's decl. and as H is a right angle we have, sine PH : radius :: tang. HC : tang. P. This analogy when the sun's decl. is $7^{\circ} 9'$, as it is, on Oct. 12th. gives $18^{\circ} 8'$ nearly for the angle P; and this converted to time gives $1 \text{h. } 12 \text{m. } \frac{8}{3}$, for the duration of the twilight at the equator on October 12th.

As to the duration of the twilight on the same day in lat. $52^{\circ} 12' N.$ it is given at Pa. 94, O. Gregory's *Astronomy*, and at Pa. 19, Professor Vince's *Astronomy*; both of whom state it at about $1 \text{h. } 58 \text{m.}^2$. So that the duration of twilight at the equator (which is *absolutely* the shortest twilight) is shorter than that in lat. $52^{\circ} 12' N.$ by 46m.^2 .

Remark. Hence appears the mistake of those who conceive that the common analogy for the shortest twilight is applicable to questions like this:—for, although that analogy enables us to find the

the sun's declination when the twilight is a maximum at any given latitude, yet the converse of the analogy will not assist us in finding the latitude where the twilight is a minimum, and the sun's declination given:—the problema are not one and convertible, but two and distinct.

XVII. QUESTION 317, answered by Mr. Cunliffe.

It is pretty obvious from what Mr. Simpson has delivered on the maxima and minima of geometrical quantities in the Scholium to Theorem 8, that the sides of the given triangle will be bisected at the points of contact of the greatest inscribed ellipsis. This being noticed, let ABC (fig. 654, pl. 2a.) be a given triangle with its greatest inscribed ellipsis touching the sides AB, AC and BC in the middle points D, E, and F respectively; join EF and draw CD intersecting it in d; also draw AF intersecting CD in O. Because the sides AC, BC, are bisected in E and F, the line EF is parallel to AB, which is a tangent to the curve at D, and therefore EF is bisected in d; wherefore CD passes through the centre of the ellipsis, as appears from the properties of the Conic Sections. And for the same reason AF will pass through the centre of the ellipsis, and consequently O, the intersection of CD and AF will be that centre, and OD a semi-diameter. Now between O and C take OH \equiv OD, then will DH be a diameter of the ellipsis.

And because of the parallels AB, EF,
 $CF : CB :: 1 : 2 :: dF = dE : AD :: Od : DO$, that is,
 $Od = dH : DO :: 1 : 2$, and by compof. $Dd : DO :: 3 : 2$;
but $dH : DO :: 1 : 2$, as just deduced,
whence $Dd \times dH : DO^2 :: 3 : 4$.

Let the semi-diameter OG be drawn parallel to AB; then by the property of the ellipsis

$$Dd \times dH : DO^2 :: dE^2 = \frac{AB^2}{4} : OG^2; \text{ wherefore}$$

$3 : 4 :: \frac{AB^2}{4} : OG^2 = \frac{AB^2}{3 \times 4}$, whence the semi-conjugate diameters are known and the ellipsis may be described by prob. 77. B. 1. Emerson's Conics.

The demonstration of the following THEOREM may be deduced from the foregoing solution.

The sum of the squares of two conjugate diameters of the greatest ellipse that can be inscribed in any plane triangle is equal to two-ninths of the sum of the squares of the three sides of the triangle.

For, $OD = \frac{1}{2} CD$ as is well known, and

$$CD^2 = \frac{AC^2 + BC^2}{2} - \frac{AB^2}{4}, \text{ by Simp. Geo. 11. II. whence}$$

$$OD^2 = \frac{CD^2}{9} = \frac{AC^2 + BC^2}{18} - \frac{AB^2}{86}, \text{ and from what has been deduced}$$

$$OG^2 = \frac{AB^2}{18}; \text{ by adding these together}$$

$$OD^2 + OG^2 = \frac{AC^2 + BC^2 + AB^2}{18}, \text{ and therefore}$$

$$4OD^2 + 4OG^2 = \frac{2}{9} \times (AC^2 + BC^2 + AB^2);$$

Q. E. D.

The same, by Mr. John Whitley.

Let ACB (fig. 656, pl. 9a.) be the given triangle, bisect AB in D , and join CD ; suppose $DsSm$ the greatest inscribed ellipse; draw the conjugate diameter ST and the tangent ST parallel to AB , draw also SE parallel to BC .

Now by similar triangles

$$DC : DR :: DS : DE, \text{ alternately}$$

$$DC : DS :: DB : DR :: DB^2 : EDB = (DB - ST) \cdot DR = DB^2 - DB \cdot ST$$

But by Emerson's Conics, Prop. 47, on the ellipse,

$$DB \times ST = om^2; \text{ wherefore}$$

$DC : DS :: DB^2 : DB^2 - om^2 :: DC \cdot om : DS \cdot om = \text{a maximum}$ by the question. Consequently

$DB \cdot DS \cdot om = (DB^2 - om^2) \cdot DC \cdot om$ will be a max. but DC is constant, therefore when $DS \cdot om$ is a maximum, the solid $(DB^2 - om^2) \cdot om$, contained under one leg of a right angled triangle and the square of the other will be a maximum; which is the case when $om^2 = \frac{1}{2} DB^2$ (See Simp. Geom. Thea. 18. max. et min.). Hence $DS = \frac{1}{2} DC$.

Now

Now let $s = \sin$ of the angle CDB; then will

$$DS \times nm \times s = \frac{1}{2} DC \times 2\sqrt{\frac{1}{3} DB^2 \times s} = \frac{4DC \cdot DB \cdot s}{9} \sqrt{3} = \text{area},$$

$$\text{and } nm^2 + DS^2 = \frac{4DB^2}{3} + \frac{4DC^2}{9} = \text{sum of the squares of}$$

the sides of a parallelogram circumscribing the ellipsis DmSm; let the former be taken equal to $2A$ and latter equal to $4B$; also let $T =$ the transverse and $C =$ the conjugate diameters of the ellipsis. Then per Conics, $T \times C = 2A$, and $T^2 + C^2 = 4B$; therefore

$T = \sqrt{(B+A)} + \sqrt{(B-A)}$ and $C = \sqrt{(B+A)} - \sqrt{(B-A)}$, which are general Theorems for ascertaining the principal diameters of the greatest ellipsis, that can be inscribed in a given triangle.

Cor. 1. If the ellipsis touch the sides of the triangle in D, Q, and R, then will $AR = CR$, and $BQ = QC$.

Cor. 2. The point O which is the centre of the ellipsis is the centre of gravity of the triangle.

XVIII. QUESTION 318, answered by Mr. Cunliffe.

Let $a^2 = 1$, and $b^2 = 1$ denote the two numbers, for each of these when increased by 1 will manifestly be a square; but their sum and difference also when increased by 1 must be squares; that is $a^2 + b^2 = 1$, and $a^2 - b^2 + 1$ must each be a square.

Put $a^2 + b^2 = 1 = c^2$, and $a^2 - b^2 + 1 = d^2$, and by adding these two together $2a^2 = c^2 + d^2$, from whence it appears that c^2 , a^2 , and d^2 are three squares in arithmetical proportion. Therefore we may put

$c = r \times (m^2 - n^2 + 2mn)$, $a = r \times (m^2 + n^2)$, and $d = r \times (n^2 - m^2 + 2mn)$; but $a^2 + b^2 - 1 = c^2$; whence $b^2 = c^2 - a^2 + 1 = 4r^2mn \times (m^2 - n^2) + 1$, by writing for c and a their foregoing values.

Assume $b = 2rs - r$, then

$$b^2 = (2rs - 1)^2 = 4r^2s^2 - 4rs + 1 = 4r^2mn \times (m^2 - n^2) + 1.$$

Whence

Whence $r = \frac{s}{s^2 - mn \times (m^2 - n^2)}$, where s , m , and n may be taken at pleasure.

EXAMPLE I.

Take $m = 2$ and $n = 1$, then $r = \frac{s}{s^2 - 6}$, whence it is obvious enough, that if we take $s = 3$, then $r = 1$; and from what has been laid down $a = r \times (m^2 + n^2) = 5$, and $b = ars - 1 = 5$, and hence $a^2 - 1 = 24$, and $b^2 - 1 = 24$, in which case the two numbers are equal to each other.

EXAMPLE II.

Take $m = 3$ and $n = 2$, then $r = \frac{s}{s^2 - mn \times (m^2 - n^2)} = \frac{s}{s^2 - 30}$ where it is pretty plain that if we take $s = 6$, then $r = 1$, and hence $a = r \times (m^2 + n^2) = 13$, and $b = ars - 1 = 11$; and hence again $a^2 - 1 = 168$ and $b^2 - 1 = 120$, being two numbers that will answer.

EXAMPLE III.

Take $m = 4$ and $n = 3$, then $r = \frac{s}{s^2 - 84}$, where if s be taken = 9, then $r = -3$; and $a = r \times (m^2 + n^2) = -75$ and $b = ars - 1 = -55$, and hence $a^2 - 1 = 5624$ and $b^2 - 1 = 3024$, which are Mr. Bonnycastle's numbers.

EXAMPLE IV.

Take $m = 5$ and $n = 3$, then $r = \frac{s}{s^2 - 340}$, whence it is not difficult to perceive, that if we take $s = 16$, then $r = 1$, and

$a = r \times (m^2 + n^2) = 34$ and $b = 2rs - 1 = 31$;
and from these $a^2 - 1 = 1155$ and $b^2 - 1 = 960$, which are
another pair of numbers that will answer.

Very general formulæ for whole numbers that will answer the question may be obtained as follows. We have before found that

$$b^2 = 4r^2 mn \times (m^2 - n^2) + 1 = 4r^2 m^2 n - 4r^2 mn^2 + 1$$

assume $b = 2r^2 mn^2 - 1$, then

$$b^2 = (2r^2 mn^2 - 1)^2 = 4r^4 m^2 n^4 - 4r^2 mn^2 + 1$$

$$= 4r^2 m^2 n - 4r^2 mn^2 + 1.$$

Whence $m = r^2 n^2$, $b = 2r^2 mn^2 - 1 = 2r^4 n^3 - 1$, and
 $a = r \times (m^2 + n^2) = r \times (r^4 m^2 + n^2) = r^2 n^2 \times (r^2 n^2 + 1)$,
where r and n may be taken at pleasure.

EXAMPLE I.

Suppose $r = 2$ and $n = 1$, then $a = 34$ and $b = 31$, which agrees with what was obtained in the fourth example, by the first method of solution.

EXAMPLE II.

Suppose $n = 2$ and $r = 1$, then $a = 1028$ and $b = 541$, whence $a^2 - 1 = 1056783$ and $b^2 - 1 = 261120$, which are two other numbers that will answer.

Ingenious solutions were also received from Messrs. Boole, Collins, Hearding, and Whitley.

XIX. QUESTION 819, answered by Mr. Gregory.

Fig. 691, Pl. 33. Let Vv be a ray from the sun, touching V the vertex of the cone $VABD$, and v the extremity of the shadow. Let $RGSH$, $RG\Delta H$, &c. be sections of the cone, whose axes RS , RS , &c. are parallel to Vv , and whose whole planes coincide with rays from the sun; these sections will manifestly be ellipses so long as the sun's alt. is less than the angle ABV of the cone.

cone, and in no other case can there be a shadow. Produce RS, RS, &c. to g , g , &c. and draw gh , gh , &c. perpendicular to Av , and respectively equal to GH, GH, &c. the conjugate axes of the several ellipses: then (since the solar rays may, so far as relates to this case, be reckoned parallel) will each of these ellipses be projected into parallel right lines, whose extremities are at gh , gh , &c. Now draw $VOOO$ bisecting all the transverse axes, RS, RS, &c. which, as these axes are parallel to each other, will obviously be a right line. And since HG, HG, &c. are similar chords in circles whose dimensions increase as their respective distances VO , VO , &c. from the vertex they will be proportional to those distances: that is,

$VO : VO :: HG : HG :: hg : hg$. But by reason of the parallels Vv , Ro , &c. it is

$VO : VO :: vo : vo$; consequently $vo : vo :: hg : hg$.

And since this is the case in every parallel position of RGHS, and the corresponding projections hg , hg , &c. it is evident that they are the bases to a series of similar triangles, whose common vertex is v , and whose other sides are $vggg$, $vhhh$; that is, it is evident that $vggg$, $vhhh$, the lines bounding the shadow are right lines. But lines bounding the shadow, cannot, as is clear from the nature of such projections, pass *at a distance* from the base of the cone, as vI , vK ; and they cannot, from what is done above, be other than right lines: therefore, *the lines bounding the shadow of a cone, standing in the sun-shine, are right lines drawn from the vertex of the shadow, and touching the base of the cone.* Q. E. D.

XX. QUESTION 320, answered by Mr. Cunliffe.

The construction of the question will be more neat if the following problem be first laid down as a Lemma.

In a given circle, whose centre is O , (fig. 688. pl. 33.) to draw a chord AB parallel to a right line OQ given by position, so that drawing OM perpendicular thereto, the sum of AB and MO may be of a given length or a maximum.

CONSTRUCTION. Take OP perpendicular to OQ , and equal to the given sum of the chord, and perpendicular thereto from the centre O ; also take $OQ = \frac{1}{2}OP$, and draw PQ cutting the circle in B , B' then through either of the points B , B' draw the chord BA parallel to OQ , cutting OP in M , and the thing is done.

DEMON.

DEMONSTRATION. Because $OQ = \frac{1}{2}OP$,
and OQ and MB are parallel,
therefore $MB = \frac{1}{2}PM$, or $2MB = AB = PM$,
whence $AB + MO = PM + MO = PO$ the given length
by the construction.

Limit. When PO the sum of the chord and perpendicular
is a maximum, PQ will just touch the circle in B , and the radius
 OB will be perpendicular thereto by Euc. 18. III. hence and from
what has been deduced $PB = 2OB$ from whence the line PB in
the limiting case may be easily drawn.

The construction of the original question may be as follows :

The sum of the squares of the sides, by the question, has a given
ratio to the rectangle under the perpendicular and a given line ;
Wherefore it is pretty obvious, that the sum of the squares of the
sides must be equal to the rectangle under the perpendicular and
a given line, which given line let be denoted by $4L$.

CONSTRUCTION. Take a right line Od (fig. 689. pl. 33.)
equal to half the given difference of the segments of the base, and
make the right angled triangle dOG such that the hypotenuse
 $dG = L$; then with the centre O , and radius OG describe a
circle, in which by the preceding problem draw the chord BA
parallel to Od so that $AB + MO$ may be a given length or a
maximum.

Through d draw dD parallel to OM meeting AB in D , and
in Dd produced take $dC = L$, join CA , CB and ACB is the re-
quired triangle.

DEMONST. Draw Md , MC and the radius OB .

$$\begin{aligned} \text{Then } \overline{MB}^2 &= \overline{OB}^2 - \overline{OM}^2 = \overline{OG}^2 - \overline{OM}^2 \\ &= \overline{dG}^2 - \overline{dM}^2 = \overline{dC}^2 - \overline{dM}^2 \end{aligned}$$

by Euc. 47. I. and Simpson's Geometry, theor. 9. b. 2.

Also $\overline{MC}^2 = \overline{dC}^2 + \overline{dM}^2 + 2dC \times dD$ by Euc. 12. II.
and adding the two foregoing expressions together,

$$\begin{aligned} \overline{MB}^2 + \overline{MC}^2 &= 2(dC)^2 + 2dC \times dD \\ &= 2dC \times DC = 2L \times DC : \text{ from whence and theorem 21.} \\ &\quad \text{b. 2. Simpson's Geometry.} \end{aligned}$$

$$2(MB)^2 + 2(MC)^2 = \overline{AC}^2 + \overline{BC}^2 = 4L \times DC.$$

Moreover $BA + Dd$ is a given length, or a maximum by
the construction.

Therefore $BA + Dd + dC = BA + DC$ is a given length,
or a maximum, because dC is a given length.

XXI. QUESTION 321, answered by Mr. Whitley.

Let ACB (fig 690. pl. 33.) be any plane triangle, AE , BF and CD lines drawn from the angles to bisect the opposite sides, and intersecting each other in Q , and let QI , QG and QH be drawn perpendicular to the sides AB , AC and BC . Then will the solid $QI \cdot QG \cdot QH$ be a maximum, and three times the sum of the squares of AQ , BQ , CQ equal to the sum of the squares of AC , BC , AB .

For draw FE , DF and DE , then because $CF = AF$ and $CE = BE$, $CE : CF :: BE : AF :: CB : AC$, therefore FE is parallel to AC . In the same way it is shewn that DF is parallel to BC and DE to AC .

Wherefore $FE = DB = AD$, $DF = BE = CE$, and $DE = AF = CF$.

Again, by similar triangles $FE : QE :: AB : AQ$,
hence it follows that as AB is $= 2EF$,

AQ will be $= 2QE$, and therefore $AQ = \frac{2}{3}AE$.

In like manner it is shewn that

$BQ = \frac{2}{3}BF$, and $CQ = \frac{2}{3}DC$.

Wherefore $AQ^2 + BQ^2 + CQ^2 = (AE^2 + BF^2 + DC^2) \times \frac{4}{9}$

$= \{ \text{by Simpson's Geometry II. 11, } (\frac{1}{4}AC^2 + \frac{1}{4}BC^2 - BE^2) + (\frac{1}{4}AB^2 + \frac{1}{4}BC^2 - AF^2) + (\frac{1}{4}AC^2 + \frac{1}{4}BC^2 - AD^2) \} \times \frac{4}{9}$

$= (AC^2 + BC^2 + AB^2 - BE^2 - AF^2 - AD^2) \times \frac{4}{9}$

$= (\frac{1}{2}AB^2 + \frac{1}{2}BC^2 + \frac{1}{2}AC^2) \times \frac{4}{9} = \frac{1}{2}AB^2 + \frac{1}{2}BC^2 + \frac{1}{2}AC^2$.

Consequently $3AQ^2 + 3BQ^2 + 3CQ^2 = AC^2 + BC^2 + AB^2$.

Again, let CS be drawn perpendicular to AB ;

then by similar triangles $CS : QI :: CD : QD$;

but $DQ = \frac{1}{3}CD$ (by above), theref. also $QI = \frac{1}{3}CS$.

Wherefore the ΔAQB is equal to $\frac{1}{3}$ of the ΔACB .

In like manner it may be shewn that the triangles AQC , BQC are each equal to one-third of the triangle ACB , and consequently the triangles AQB , AQC , and BQC , are equal to each other; therefore $2AQB \times 2AQC \times 2BQC$ is, by Simpson's Geometry, Theorem 16, a maximum;

That is $(DB \cdot QI) \times (FC \cdot QG) \times (CE \cdot QH) = \text{a maximum}$, and because DB , FC , CE , are here supposed given lines, the solid contained under $QI \times QG \times QH$ is also a maximum. *Q. E. D.*

XXII.

XXII. QUESTION 322, *answered by Mr. W. Wallace.*

It is evident that the centre of the given circle is such a point as satisfies the conditions of the question; but let us investigate whether another point can be found, such as is required.

ANALYSIS. Suppose Q (fig. 671, pl. 32.) to be the point which may be found and that DQ produced cuts the circle again in A , then by hypothesis the rectangle $CQ \times QD$ is given; but Q being a determinate point, from the nature of the circle $AQ \times QD$ is given, therefore the ratio of $CQ \times QD$ to $AQ \times QD$ is given and hence CQ must have to AQ a given ratio.

Join PQ cutting the circle in B and E ; if we now suppose the point C to approach to B , the point A will also approach to B , so that when CQ coincides with BQ , AQ also coincides with BQ ; thus it appears that the given ratio of CQ to AQ can be no other than that of equality, and since the line BQ must lie between AQ and CQ , however near these lines may be to each other, it is evident that BQ must pass through F the centre of the circle; thus the arch AB is equal to the arch BC , and if AF , CF be drawn to the centre, the angle AFB is equal to CFB therefore the angle AFC is double the angle AFB or AFP ; but AFC being an angle at the centre is also double the angle ADC or ADP at the circumference, therefore the angles AFP , ADP are equal, hence the points A , F , D , B are in the circumference of a circle and the rectangle $PQ \times QF$ is equal to $AQ \times QD$, that is to $BQ \times QF$, to each of these rectangles add QF^2 , and we have $PF \times FQ = BF^2$. The point Q may therefore be found by the following

CONSTRUCTION.

Let F be the centre of the given circle, and P the given point. Join PF and take the point Q between P and F so that FQ may be a third proportional to PF and FB the radius of the circle.

The same, by Mr. Cunliffe.

Through the centre O (fig. 692, pl. 33.) draw the right line PAB cutting the circle in A and B ; then upon PO take PQ a fourth proportional to PO , PB , and PA , and Q is the point.

DEMONSTRATION. Draw the radii CO, DO ; then by construction $PO : PB :: PA : PQ$, whence $PO \times PQ = PA \times PB$; but by Euc. 36. III. $PA \times PB = PC \times PD$, and consequently $PO \times PQ = PC \times PD$, and therefore a circle will pass through the points C, Q, O, D. Therefore $\angle PDQ = \angle COQ$ by Euc. 21. III, and consequently $\angle PQD = \angle PCO$. Also $\angle CQO + \angle PDO = \angle CQO + \angle OCD = \angle COQ + \angle OCD = 2$ right angles by Euc. 13. I, and 22. III, and taking away $\angle OCD$ leaves $\angle CQO = \angle PCO = \angle PQD$, and consequently $\angle QCO = \angle QPD$; therefore the triangles CQO and PQD are similar, therefore $PQ : DQ :: CQ : QO$, whence $CQ \times DQ = PQ \times QO$ a given space.

Mr. Whitley *answ. red. it.*

XXIII. QUESTION 323, answered by Mr. Cunliffe.

Fig. 693. pl. 33. By a well known property of triangles $(AC - BC)^2 = 4DQ \times EF$, and therefore the solid $(AC - BC)^2 \times DC = 4DQ \times DC \times EF$, and when this solid is a maximum, the rectangle $DC \times EF$ will be a maximum, because $4DQ$ is given ; also when the rectangle $DC \times EF$ is a maximum, its square $DC^2 \times EF^2$ must obviously be a maximum.

Draw FC ; then by Euc. 13. II. $DC^2 + 2DF \times EF = DF^2 \times FC^2$, and by a well known property

$$FQ \times EL = 2OF \times EF = FC^2$$

the difference of which is

$DC^2 + 2OD \times EF = DF^2 = 2OD \times L$, by taking the line L a third proportional to $2OD$ and DF ; whence

$$DC^2 = 2OD \times L - 2OD \times EF = 2OD \times (L - EF)$$

Therefore $DC^2 \times EF^2 = 2OD \times (L - EF) \times EF^2$,

and when this expression is a maximum,

$(L - EF) \times EF^2$ will be a max. because $2OD$ is given.

Now when $(L - EF) \times EF^2$ is a maximum, $EF = \frac{1}{3}L$, as appears from Theorem 17th Simpson on the maxima and minima ; therefore $3EF = 2L$.

$$\text{Whence } 3DO \times EF = 2DO \times L = DL^2$$

Q. E. D.

The

The same, by Mr. Whitley, of Attercliffe.

Let fig. 694, pl. 33, be constructed as per quest. and join AF, CF, AO, AQ, and to the point A draw the tangent AP meeting the diameter FQ in P, also bisect PD in S. Now because the angles PAO, QAF are right angles (Euc. §1, 18, III.) the rectangles PD \times DO, QD \times DF are each equal to the square of AD (Euc. Cor. 8, VI.) therefore the rectangle PD \times DO = QD \times DF = 2DS \times DO, add twice the rectangle DF \times DO, to each, then $(QD + 2DO) \times DF = (2DS + 2DF) \times DO = 2FS \times DO$; but $QD + 2DO = DF$, therefore $DF^2 = 2FS \times DO$.

Now let GC be taken equal to the difference of the sides AC, BC; then it will be manifest from what is shewn in Prop. 98. of Simpson's Data that

$AF : AB :: CF : CG$, and therefore

$AF^2 : AB^2 :: CF^2 : CG^2 :: CF^2 \times CD : CG^2 \times CD$.

Now since AB and QF are constant, by the hypothesis, AF is so too, and therefore when $CF^2 \times CD$ is a maximum, $CF^2 \times CD$ will be so likewise; but (by Cor. Euc. 8, VI.) the rectangle QF \times EF = CF^2 ; wherefore $CF^2 \times CD = QF \times EF \times CD$, and, because QF is constant, when the solid $CF^2 \times CD$ is a maximum, the rectangle EF \times CD, and consequently EF \times CD = 2OD \times ES \times EF (by Prop. VI. Dr. Stewart's General Theorems) will be so too; and therefore since 2OD is constant, the solid EF \times ES will be a maximum, which is the case when when EF = 2ES (vide Simpson's Geometry, Theo. 17, Max. et Min.);

wherefore 3EF = CES = 2FS, and 3EF \times OD = 2FS \times OD; but it has been shewn that $DF^2 = 2FS \times OD$; wherefore 3EF \times OD = DF^2 .

Q. E. D.

XXIV. QUESTION 324, *answered by Mr. John Whitley.*

Let NnmM (fig. 695, pl. 33.) be a conic section; and let the lines be drawn as per question, also let PM, PN be drawn, the latter meeting AB in v, and join nm. Now by conics nm is parallel to AB. And by similar triangles

$vn : vC :: nN : NM$, also $vC : vN :: nm : nN$, wheref.
 $vn : vN :: nm : NM :: Pn : PN$ (by simi. triangles).

That is the straight line PN is harmonically divided by the parallels nm , AB, in the points n , v ; and therefore by Cor. 2. to Props. 71, 64, 38; Books 1, 2, and 3, of Eudemus's Conics, the straight lines joining the points PA, PB, will be tangents to the Conic Sections at A and B.

The same; answered by Limenus, the Proposer.

LEMMA 1. Let lines be drawn from the extremities of any ordinate to a conic section through a point in the diameter; and the line joining their intersections with the curve will be parallel to the ordinate.

LEMMA 2. Let MN (fig. 652, pl. 32) and m_n be two parallel lines, and let Mm and Nn meet in P, and Mn and Nm in C, then PC being joined will bisect the parallels Mm and Nn .

Join PC to meet MN in D, and it follows from Lemma 1, that mn drawn will be parallel to MN, and therefore PC bisects MN by Lemma 2, and P is consequently in the diameter appertaining to AB and MN. Also because AC is parallel to MN and CD bisects MN in D, the lines AC, MC, DC, and NC are harmonicals; and they intersect PM in P, m , a , M, and PN in P, n , b , N; therefore Pa , and Pb are harmonical means between the segments PM, Pm , and PN, Pn . And therefore all other right lines drawn from the point P to AB will be harmonical means between the segments intercepted by P and the curve (Maclaurin De Lin. Geom.). But PA meeting AB and the curve in the same point A, the other point of intersection of PA with the curve necessarily coincides with the first; and therefore PA is a tangent at A; and for the same reason PB touches the curve in B.

Mr. Cunliffe also favoured us with an ingenious demonstration of this Proposition.

XXV. QUESTION 325, answered by Mr. Cunliffe.

In fig. 667, pl. 32, take any two points B and a in the diameter EF of a semicircle and draw from thence the right lines BC, AC , to any point C, in the circumference; draw the radius OC and demit CD perpendicular to EF; also upon EF take $AD = aD$

aD and join AC . Then Ba is evidently the difference of the segments of the base made by the perpendicular CD in the triangle ACB .

Take the line L such that the rectangle $OB \times L = OC^2 - OB \times Oa$, then $OC^2 = OB \times (L + Oa)$; whence by Euc. 12. II. $BC^2 = OC^2 + OB^2 + 2OB \times OD$
 $= OB \times (L + Oa) + OB^2 + 2OB \times OD$, and $aC^2 = AC^2 = OC^2 + Oa^2 + 2Oa \times OD$
 $= OB \times (L + Oa) + Oa^2 + 2Oa \times OD$
 $= OB \times L + OB \times Oa + Oa^2 + 2Oa \times OD$.

Now let S denote a space to which the square of BC has the ratio of DB to Oa , that is

$$\begin{aligned} OB : Oa :: BC^2 &= OB \times (L + Oa) + OB^2 + 2OB \times OD \\ &: Oa \times (L + Oa) + OB \times Oa + 2Oa \times OD \\ &= Oa \times L + Oa^2 + OB \times Oa + 2Oa \times OD \\ &= S, \text{ whence} \end{aligned}$$

$$\begin{aligned} AC^2 - S &= OB \times L - Oa \times L = (OB - Oa) \times L \\ &= Ba \times L, \text{ and hence the following construction is derived.} \end{aligned}$$

Take the right line Ba equal to the given difference of the segments of the base and bisect the same in m , in Ba take OB to Oa in the given ratio mentioned in the question, and O will be a given point. Again take a right line L such that the rectangle $Ba \times L$ may be equal to the given excess of the square of one side above the space to which the square of the other side has a given ratio; then in OB take OF such, that $OF^2 = OB \times (L + Oa)$; with the centre O and radius OF describe a semi-circle ECF the circumference of which will be the locus of the vertex C of the triangle. All therefore that now remains to be done is to draw the perpendicular DC so that the solid $AB \times DC^2 = 2mD \times DC^2$ may be a maximum, or that $mD \times DC^2$ may be a maximum, which is obviously the same thing as within the given segment of the sphere to inscribe the greatest cylinder possible; and the method of doing this is too well known to need repeating here; it belongs to the Scholium to Theo. 19, Simpson on the Maxima and Minima.

XXVI. QUESTION 326, *answered by the Proposer.*

From the nature of *converging* series, it is evident that in the form proposed, x must necessarily be always less than unity.

And

And it is evident that the coefficients, $a, b, c, \&c.$ must not only be in a regular decreasing progression, but in order that the terms of the series may continue *fine fine*, they must also be fractional numbers, or the reciprocals of an increasing progression of integers. Under these circumstances (for in no other can the *infinite* summation be possible) we may, by the assistance of **NEWTON**'s residual theorem, always obtain an expression for the value of the proposed infinite series. Thus, if $a, b, c, \&c.$ be expounded by the reciprocals of the natural numbers 1, 2, 3, &c. the sum of the series resulting from the application of the theorem adverted to, will be had from this simple formula.—

Subtract x from unity, divide unity by the remainder, from the nth root of the quotient take unity, multiply the remainder by n, and divide the product by x, the quotient will give the sum of the series ad infinitum; when x is any large power of 10. In like manner may general expressions be reduced from the said residual theorem with other values *ad libitum* of the coefficients $a, b, c, \&c.$ under the above limitations.

It is very remarkable that the above formula is obviously equal to *Napier's* logarithm of the reciprocal of $1 - x$ divided by $x.$

Hence, for example if x be $\frac{9}{10}$, the sum of the series will be

expressed by—the log. of 10 divided by 9, equal to 2.558427.

If x be $\frac{98}{99}$, the sum will be obtained by dividing the log. of 99

by the compound repetend .98, equal to 4.642; and thus with any other values of x than unity.

Cavallerius refers the proposer of this question to pa. 222, 223, &c. *Simpson's Algebra*, 2d edit. where he will find the method of summing the proposed series in a variety of cases, when the law of the coefficients is given.

XXVII. QUESTION 327, answered by Mr. Cunliffe.

In the present case $y = b$, and the equation of the curve becomes $x = \frac{b-y}{2y} \times h. 1. \left(\frac{b+y}{b-y} \right),$

and

and taking the fluxions

$$x = \frac{ly}{y} - \dot{y} \times \left(\frac{l^2 + y^2}{2y} \right) \times h. l. \left(\frac{l+y}{l-y} \right), \text{ and hence}$$

$$yx = ly - \frac{\dot{y}}{2y} \times (l^2 + y^2) \times h. l. \left(\frac{l+y}{l-y} \right)$$

$$= ly - \frac{y\dot{y}}{2} \times h. l. \left(\frac{l+y}{l-y} \right) - \frac{l\dot{y}}{2y} \times h. l. \left(\frac{l+y}{l-y} \right)$$

= the fluxion of the area.

$$\text{And fluent of } yx = \begin{cases} ly - \text{fluent of } \frac{y\dot{y}}{2} \times h. l. \left(\frac{l+y}{l-y} \right) \\ - \text{fluent of } \frac{l\dot{y}}{2y} \times h. l. \left(\frac{l+y}{l-y} \right). \end{cases}$$

Now the fluent of $\frac{y\dot{y}}{2} \times h. l. \left(\frac{l+y}{l-y} \right)$ is

$$= \frac{1}{2}ly - \frac{1}{4} \times (l^2 - y^2) \times h. l. \left(\frac{l+y}{l-y} \right)$$

and the fluent of $\frac{l\dot{y}}{2y} \times h. l. \left(\frac{l+y}{l-y} \right)$ is

$$= l^2 \times \left(\frac{y^1}{l} + \frac{y^3}{9l^3} + \frac{y^5}{25l^5} + \frac{y^7}{49l^7} + \frac{y^9}{81l^9} + \text{ &c.} \right)$$

$$\text{Whence the fluent of } yx = \begin{cases} ly - \text{fluent of } \frac{y\dot{y}}{2} \times h. l. \left(\frac{l+y}{l-y} \right) \\ - \text{fluent of } \frac{l\dot{y}}{2y} \times h. l. \left(\frac{l+y}{l-y} \right) \end{cases}$$

$$= \left\{ \frac{1}{2}ly + \frac{1}{4} \times (l^2 - y^2) \times h. l. \left(\frac{l+y}{l-y} \right) \right\}$$

$$= \left\{ -l^2 \times \left(\frac{y^1}{l} + \frac{y^3}{9l^3} + \frac{y^5}{25l^5} + \frac{y^7}{49l^7} + \frac{y^9}{81l^9} + \text{ &c.} \right) \right\}$$

but this expression ought to vanish when $y = l$, therefore the correct expression for the area is

=

$$\begin{aligned}
 &= \left\{ \begin{array}{l} l^2 \times (1 + \frac{1}{9} + \frac{1}{25} + \frac{1}{49} + \frac{1}{81} + \text{etc.}) \\ - \frac{l}{2} + \frac{ly}{2} + \frac{1}{2} \times (l^2 - y^2) \times \text{h. l.} \left(\frac{l+y}{l-y} \right) \\ - l^2 \times \left(\frac{y}{l} + \frac{y^3}{9l^3} + \frac{y^5}{25l^5} + \frac{y^7}{49l^7} + \frac{y^9}{81l^9} + \text{etc.} \right) \end{array} \right. \\
 &= \left\{ \begin{array}{l} \frac{l^2 q^2}{2} - \frac{l}{2} + \frac{ly}{2} + \frac{1}{2} \times (l^2 - y^2) \times \text{h. l.} \left(\frac{l+y}{l-y} \right) \\ - l^2 \times \left(\frac{y}{l} + \frac{y^3}{9l^3} + \frac{y^5}{25l^5} + \frac{y^7}{49l^7} + \frac{y^9}{81l^9} + \text{etc.} \right) \end{array} \right.
 \end{aligned}$$

because $\frac{l^2 q^2}{2} = l^2 \times (1 + \frac{1}{9} + \frac{1}{25} + \frac{1}{49} + \frac{1}{81} + \text{etc.})$ as appears

from Art. 6. of Landen's 5th Memoir; whence q denotes the length of the quadrantial arc of a circle whose radius is 1. And when $y = 0$, or when the chain is completely stretched along the horizontal line AB, the expression for the area will then be

$$\frac{l^2}{2} \times (q^2 - 1) = l^2 \times 7337005.$$

The area may also be expressed in other particular cases of the value of y , without series from what is deduced at Art. 40. Postscript to Landen's 5th Memoir.

The same, by Mr. John Surtees.

Let $c = 3.1416$, $z = \text{AV} = \text{half the length of the chain}$,
 $x = \text{SV}$, and $y = \text{AS} = \frac{z^2 - x^2}{2x} \times \text{h. l.} \left(\frac{z+x}{z-x} \right)$.

Then the Fluxion of the area $= yx =$

$$\frac{z^2 x}{2x} \times \text{h. l.} \left(\frac{z+x}{z-x} \right) - \frac{x^2 x}{2} \times \text{h. l.} \left(\frac{z+x}{z-x} \right).$$

The

The fluent
of which is

$$\left\{ \begin{array}{l} zx + \frac{x^3}{9z} + \frac{x^5}{25z^3} + \frac{x^7}{49z^5} \text{ &c.} \\ + \frac{z^3 - x^3}{4} \times h. l. \left(\frac{z+x}{z-x} \right) - \frac{zx}{2} \end{array} \right.$$

And when $x = z$, the fluent is

$$\begin{aligned} &= z^2 \times \left(1 + \frac{1}{9} + \frac{1}{25} + \frac{1}{49} \right) \text{ &c.} - \frac{z^2}{2} = z^2 \times \frac{c^4 - 4}{8} \\ &= z^2 \times .73369 = \text{the area.} \end{aligned}$$

W. W. R.

XXVIII. QUESTION 328, *answered by Mr. I. H. Hearding*

Put $d = 25$ inches, the distance of the axis of motion from the centre of the ball, and $r = 5$ inches, the ball's radius; then, by Emerson's Mechanics, Prop. 58. the distance of the centre of oscillation from the point of suspension, or the true length of the pendulum, is $= d + \frac{2rr}{5d} = 25\frac{1}{3}$ inches. Let AC (fig. 668, pl. 32.) represent the wire when stretched out tight in an horizontal position, AB its position when it first becomes perpendicular to the same; and, from any point D, in the arch CBH, wherein the vibrations are made, draw Dd \parallel CH; and let AB = AC be put = a , Bd = x , and the arch BD = z ; then, by the nature of the circle, $z = \frac{ax}{\sqrt{(2ax - xx)}}$; and, since the fluxion

of the time through BD is as $\frac{z}{\sqrt{[Ad]}}$ (see Art. 207, Simpson's Fluxions) it will be here truly expressed by

$$\begin{aligned} \frac{ax}{\sqrt{[a-x] \times \sqrt{[2ax - x^2]}}} &= \frac{\sqrt{[\frac{1}{2}a] \times r}}{\sqrt{[ax - xx]}} \times \left(1 - \frac{x}{2a} \right)^{-\frac{1}{2}} \\ &= \frac{\sqrt{[\frac{1}{2}a] \times r}}{\sqrt{[ax - xx]}} \times \left(1 + \frac{x}{2a} + \frac{3x^2}{2 \cdot 4 \cdot 4a^2} + \frac{3 \cdot 5x^3}{2 \cdot 4 \cdot 6 \cdot 8a^3} + \frac{3 \cdot 5 \cdot 7x^4}{2 \cdot 4 \cdot 6 \cdot 8 \cdot 16a^4} \right. \\ &\quad \left. \text{ &c.} \right) \end{aligned}$$

VOL. III.

Z

and

and the fluent of this, when x becomes $= a$, is $=$

$$p \sqrt{\left[\frac{1}{2}a\right]} \times \left(1 + \frac{1}{2.2.2} + \frac{3.3}{2.2.4.4.2^3} + \frac{3.3.5.5}{2.2.4.4.6.6.2^5} + \text{&c.}\right)$$

where p is $= 3.14159$ &c. Now the time of descent through the diameter BF , or chord CB , is found to be as the fluent of

$\frac{2a}{\sqrt{2a}}$, or $2\sqrt{2a}$; therefore, this is to the time of descent through the arc CDB ,

$$\text{as } \frac{4}{p} : 1 + \frac{1}{2.2.2} + \frac{3.3}{2.2.4.4.2^3} + \frac{3.3.5.5}{2.2.4.4.6.6.2^5} + \text{&c.}$$

$$(= 1.180339).$$

But the absolute time of descent through the chord BC , or diameter BF is $= \sqrt{[BF \div 193]} = 0.51237$ seconds (Simpson's Select Exercises, pa. 183, 1st. Edit.); consequently

as $1.27324 : 1.180339 :: 0.51237 \text{ sec.} : 0.474986$ seconds,
the time in which the wire will first become perpendicular to the horizon.

W. W. R.

The same, by Mr. John Smith, Alton Park.

By Dr. Hutton's Dictionary, Vol. I. pa. 268, the distance of the centre of oscillation from the point of suspension will be

$$25 + \frac{2 \times 5^2}{5 \times 25} = 25.4. \text{ Then, by the nature of pendulums,}$$

as $\sqrt{39.145} : \sqrt{25.4} :: 5 : 402865$ the time of a semi-vibration in a cycloid. But by Dr. Hutton's Select Exercises, pa. 192, the time in a cycloid is to that in a circle, when the arc of semi-vibration is a quadrant. as 1 to 1.18014; therefore as 1 : 1.18014 :: 402865 : 475437 of a second, the time required.

The same, by Mr. John Surtees.

Let $r = \frac{1}{12} \times (25 + \frac{2 \times 5^2}{5 \times 25}) = \frac{127}{60}$ feet the distance of the centre of oscillation from the point of suspension, $c =$

$\tau\sqrt{\frac{2}{3}}$ = the chord of the arch which the centre of oscillation describes, $d = \frac{c}{4^{1/2}}$, and $s = 16\frac{1}{2}$ feet.

Then $ca = \frac{1}{2}$, and per Emerson's Fluxions, page 145, the time of a semi-vibration

$$= \frac{3 \cdot 1416}{4} \sqrt{\left[\frac{9r}{2}\right] \times : 1 + \frac{cd}{2^3} + \frac{3^2 c^2 d^2}{2^6 \cdot 4^2}} \text{ &c.}$$

$$= \frac{3 \cdot 1416}{4} \sqrt{\left[\frac{254}{965}\right] \times : 1 + \frac{1}{2^3} + \frac{1 \cdot 3}{2^6 \cdot 4^2} + \frac{1 \cdot 3 \cdot 5}{2^9 \cdot 4^3 \cdot 6^1} + \frac{1 \cdot 3 \cdot 5 \cdot 7}{2^9 \cdot 4^3 \cdot 6^2 \cdot 8^1}} \text{ &c.}$$

$$= 477 \text{ seconds.}$$

W. W. R.

XXIX. QUESTION 307, answered by the Proposer.

Let x denote the required length of the lever AB , w equal 2lb. its weight per inch, and p such a power applied at B , that may produce an equilibrium. Then from the principles of motion respecting the *heavy lever*, the momentum of the weight W , added to that of the lever itself, being equated to the momentum of the power acting at B , and properly transposed, it will then appear from the equation, that p is susceptible of a *minimum*. Therefore, by the fluxionary process *Ajaxina et Minima*, we find x equal to the square root of $AC \cdot W$ divided by half of w , equal to 60 inches, the required length of the lever, when the power applied at B to raise the weight and beam will be the *least possible*.

That is, $AC \cdot W + wx \times \frac{x}{2} = px$;

or, $\frac{AC \cdot W}{x} + \frac{wv}{2} = p = AC \cdot W \times x^{-1} + \frac{w}{2}x$;

hence $\frac{w}{2}x = AC \cdot W \times x^{-2}$,

and $x = \sqrt{\frac{AC \cdot W}{\frac{1}{2}w}} = 60$.

The same result may be obtained without the aid of fluxions, from the consideration that when there is an equilibrium of power and weight in any mechanical combination, the motive force then applied will be only what is necessary to overcome the *vis inertie* and the friction of the parts.

Hence, from the common laws of motion, if the weight at C be so applied (by means of a pulley) as to raise the other end of the lever vertically, the relation of the parts when there is an equilibrium, will be expressed by an equation, which reduced, will give AB, the length of the lever, equal to 60 inches, as before.

From the above solution we see the propriety of the observation made by the ingenious Mechanician M. De Prony, in his valuable treatise *Architeture Hydraulique*, Art. 298, respecting the *Heavy Lever*, which ignorance or prejudice has laboured so strenuously to represent as absurd, — *viz.*

“Ainsi lorsqu'on voudra soulever une masse W avec un levier pesant AB, il y aura une certaine longueur à donner à ce levier, afin que le moteur qu'on y applique soit le moindre possible.”

The same, by Mr. John Surtees, Houghton-le-Spring, Durham.

Let z = the whole length of the lever in inches, then $2z$ lbs. = its weight, and of consequence half that weight will be supported at B, and $\frac{36 \times 100}{z}$ lbs. = the part of the 100lbs. supported at B, which together $= z + \frac{3600}{z}$ = a minimum.

In fluxions $\frac{d}{dz} \left(z + \frac{3600}{z} \right) = 0$. Hence $z = 60$ inches.

W. W. R.

The same, answered by Tyro Philomatheticus.

Let x = the length required, a = 36 inches, and w = weight of 100lbs. Then will aw = force of the weight, and $2x \times \frac{1}{2}x$

$\frac{1}{2}x = x^2$ = force of the lever; whence $\frac{aw + x^2}{x} =$ the power P , which, by the question is to be a minimum.

In fluxions $\frac{2x^2 \dot{x} - aw \dot{x} - x^2 \dot{x}}{x^2} = 0$, or $x^2 = aw$.

Hence $x = \sqrt{aw} = 60$ inches to length of the lever.

The same, by Mr. James Cunliffe.

If we imagine the lever AB, (fig. 669, pl. 32.) to be supported by the fulcra DA and EB in a position parallel to the horizon the weight w of 100lb. being appended at C 36 inches from A; then the question will be to determine the length of the lever AB so that the pressure sustained by the prop EB may be equal to the given weight p .

Put $AC = a$, and $AB = x$; then by the principles of mechanics, the part of the weight w sustained by the prop EB will be expressed by $\frac{AC \times w}{AB} = \frac{aw}{x}$. Also the part of the weight of the lever AB sustained by the prop EB will be expressed by $\frac{AB \times s}{2} = \frac{sx}{2}$ where s denotes the weight of the lever per inch.

Therefore $\frac{aw}{x} + \frac{sx}{2} = \frac{2aw + sx^2}{2x}$ will express the whole weight sustained by the prop EB, which is to be equal to the given weight p by the question, that is $2aw + sx^2 = 2px$, and this equation properly reduced gives $x = \frac{p}{s} + \frac{\sqrt{(p^2 - 2aw)}}{s}$.

Whence it is evident that p^2 must not be less than $2aw$; and when $p^2 = 2aw = 14400$ then the weight sustained by the prop EB will be the least possible, and in that case $x = \frac{p}{s} = .60$ inches the length of the lever AB.

XXX. OR., PRIZE QUESTION 330, *answered by*
Cavalerius.

Let BPC (fig. 700, pl. 33.) be the cycloidal curve, BO its axis, DC the base, BVD, MSC two semicircles (of the generating circle); and OS the line through the centres.

Draw EW, FX at equal distances from SO, and through K and L describe two semicircles, having their centres in SO. Then from the genesis of the curve, $RP = PI$; and because $SP = PV$, SR will be $= IV$, viz. $CH = GD$.

Torricellius and others have demonstrated that the trilineal spaces $BMSCPB$, $BVDCPB$ are equal. Thus, because $BM = CD$, $WK = LN$, $SP = PV$, $XL = KV$, &c. each figure consists, or is made up, of an infinite number of parallel right lines, alike in each; and consequently the areas must be equal.

Now in a similar manner it is proved that the curve KPL bisects the mixt-lined quadrilateral ZLKT; and that the trilineals KIP, LRP are equal; therefore the mixt-lined quadrilateral LRIT is $=$ the trilinear, LKT. Hence the required cycloidal space KIHG is equal to LRIT, $= HG$ multiplied by the height DO; viz. equal to the distance of the centres of the circles multiplied by the radius.

This space may be cut out of the circle two ways. First, because ZK, LT are equally distant from SO, the arc KT, or ZL, is equal to LT or HG, therefore the cycloidal space is equal to the arc KT multiplied by the radius of the circle, or equal to a sector having its arc double KT. Secondly, if the distance of ZK and LT be made equal to the radius, the mixt-lined quadrilateral ZLTK will be equal to the cycloidal space, and may be cut out in that form.

The same, by the Proposer, Marlouienfis.

Fig. 701, pl. 33. Let the cycloid be described as per quest. and the generating circle in the situation proposed, and also on the diameter BD, centre Z. At the intersection of the ordinates EK, FL, with the circumference of the generating circle, write

P, Q; and join ZP, ZQ. Draw also the chords BP, BQ, DP, DQ, GK, HL. Then, from the well known properties of the circle and cycloid, we have

$$\text{the cycloidal } \} = \{ BF \times FL - \text{circ. area } BQF + \text{rectilineal space } BLHD \} = \{ \text{space } FLHD + \text{circ. segm. } HL \}.$$

And in like manner

$$\text{the cycloidal } \} = \{ BE \times EK - \text{circ. area } BPE + \text{space } BKGD \} = \{ \text{rectilin. space } EKGD + \text{circ. segm. } GK \},$$

the difference of which will evidently exhibit an expression for the area of the cycloidal space KLHG required. This method is general, wherever the points E, F are taken; but, when they are at equal distances from the centre Z, as in the question, it becomes a particular case only, and the above general expression reduces by exposition to a very remarkable simple conclusion.

From the *Data*, and the properties of the figure, we have

$$BZ = ZD = ZP, EZ = ZF, EP = FQ,$$

$$\text{arc } BP = \text{arc } DQ = DG = PK, \text{arc } PQ = GH,$$

$$\text{arc } BQ = \text{arc } DP = \text{arc } BP + \text{arc } PQ,$$

$$BE = DF = BZ - EZ, BF = BZ + EZ,$$

$$EK = EP (FQ) + PK (DG) = EP + \text{arc } BP (\text{arc } DQ),$$

$$FL = EP (FQ) + \text{arc } BP (\text{arc } DQ) + \text{arc } PQ.$$

Call the area of the generating circle, A; the circular area DQF, or BPE, X; and the circ. segm. on HL, BP, or DQ, Y; and, for brevity, the proposed cycloidal space, S: And the circ. segm. on DP, BQ, or GK will be denoted by

$$\frac{1}{2}A - \text{triang. } BDQ - Y, \text{ or } \frac{1}{2}A - BZ \times EP - Y;$$

the circ. area BPQF by $\frac{1}{2}A - X$; and the rectilineal spaces FLHD, EKGD, respectively by

$$\frac{FQ}{2} \times FD + FD \times \overline{BP} + \text{arc } PQ =$$

$$\overline{BZ - EZ} \times \frac{FQ}{2} + BP + \text{arc } PQ; \text{ and}$$

$$\frac{FQ}{2} \times \overline{BE + EZ} + \text{arc } BP \times \overline{BF}.$$

Hence the former of the above expressions becomes

$$\overline{BZ + EZ} \times \overline{EP + \text{arc } BP + \text{arc } PQ} - \frac{A}{2} + X$$

+

$$+ \overline{BZ} - \overline{EZ} \times \frac{1}{2} \overline{FQ} + \text{arc } \overline{BP} + \text{arc } \overline{PQ}$$

+ Y ; and the latter

$$\overline{BZ} - \overline{EZ} \times \overline{FQ} + \text{arc } \overline{EP} - X$$

$$+ \frac{1}{2} \overline{FQ} + \text{arc } \overline{EP} (\text{arc } \overline{DQ}) \times \overline{BZ} + \overline{EZ}$$

$$+ \frac{A}{2} - \overline{BZ} \times \overline{FQ} - Y ;$$

which being expanded by multiplication, and reduced, become respectively.

$$\frac{3}{2} \overline{BZ} \times \overline{EP} + 2 \overline{BZ} \times \text{arc } \overline{BP} + \frac{1}{2} \overline{EZ} \times \overline{EP} - \frac{A}{2} + X$$

$$+ 2 \overline{BZ} \times \text{arc } \overline{PQ} + Y = \text{the cycloidal space BLHD} ;$$

and $\frac{1}{2} \overline{BZ} \times \overline{EP} + 2 \overline{BZ} \times \text{arc } \overline{EP} - \frac{1}{2} \overline{EZ} \times \overline{EP}$

$$+ \frac{A}{2} - X - Y = \text{the cycloidal space BKGD.}$$

The latter subtracted from the former, leaves

$$\overline{BZ} \times \overline{EP} + \overline{EZ} \times \overline{EP} + 2X + 2Y + 2 \overline{BZ} \times \text{arc } \overline{PQ} - A = S.$$

But $\overline{BZ} \times \overline{EP} + 2Y$ is = twice the sector \overline{BZP} ,

so is $\overline{EZ} \times \overline{EP} + 2X$ = twice the same sector;

and the quantity $2 \overline{BZ} \times \text{arc } \overline{PQ}$ is evidently = 4 times the sector \overline{ZPQ} ; therefore

$$4 \times \text{sector } \overline{BZP} + 4 \times \text{sector } \overline{ZPQ} - A = S ;$$

or, because 4 sector $\overline{BZQ} = A + 2$ sector \overline{PZQ} ,

twice the sector \overline{PZQ} is = the cycloidal space \overline{KLHG} .

Hence, since \overline{GH} is equal the arc \overline{PQ} , the concise theorem required is — *The product of the semidiameter of the generating circle into the distance \overline{GH} is equal the cycloidal space contained within the arcs \overline{KG} and \overline{LH} ; and the cutting off a space from the generating circle equal to the cycloidal space geometrically is obvious, being the circular sector on twice the arc \overline{PQ} .*

Q. F. O.

The same, by Mr. Wallace, of the Royal Military College.

Fig. 702, pl. 33. Instead of supposing the points E and F equally distant from the centre, let us suppose them taken anywhere

where in the axis. Let EK, FL, meet the generating circle in M and N. Draw the chords DM, DN, GK, HL; then from the nature of the curve DM, GK are parallel, also DN, HL. Now it was first shewn by Dr. Wallis (in his *Treatise De Motu* Cap. V. Prop. 20.) that if FL be any ordinate to the axis, meeting the generating circle in N, and LH be drawn parallel to the chord DN, meeting the base in H, the cycloidal area BKLHD is triple the area contained by the arch BMN, the axis BD, and the chord DN, to these let the equal segments H_pL , DPN of the generating circle be added, and the mixtilineal area BKL_pHD will be equal to half the generating circle together with twice the trilineal area $BMND$. For the same reason the mixtilineal area $BKqGD$ is equal to half the generating circle together with the trilineal area BMD , therefore, taking the latter equation from the former, the proposed cycloidal space L_pHGqK is double the area contained by the chords DM, DN and the arch MN. Hence the Theorem, as well as the geometrical method required in the question is obvious, not only for that particular case, but for any given positions of the generating circle whatever.

Ingenious solutions to this question were also received from Messrs. Cunliffe, Surtees, and Whitley.

The Medal for solving the Mathematical Prize Question is decided in favour of Mr. JOHN SURTEES, who will please to send for it to Mr. GLENDINNING's.

ARTICLE XXII.

On the Quadrature of the Circle.

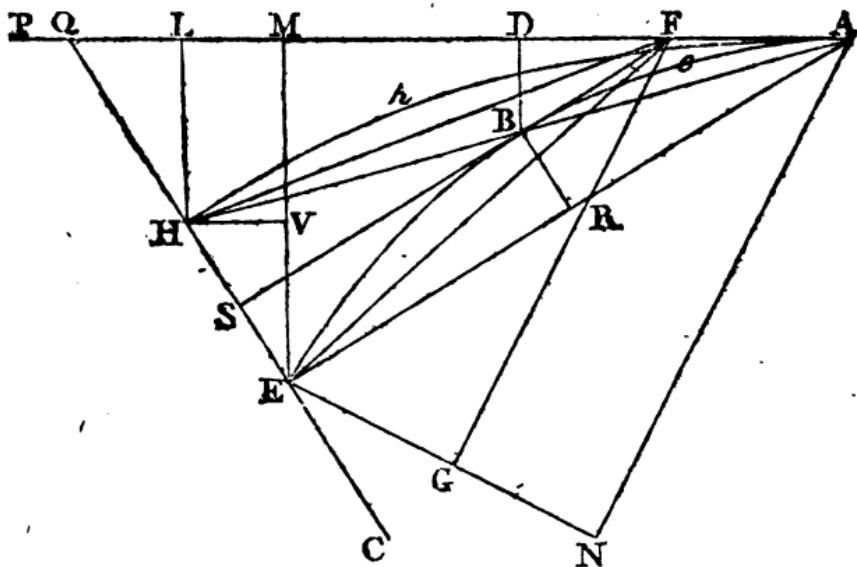

By Mr. Benjamin Gompertz, London.

A certain Author attempting to square the circle expresses himself to the following effect.

"If a tangent be drawn to a given circle, and from the point of contact a line be drawn through the centre and produced indefinitely on that side of the tangent where the centre of the circle is, and

and there be taken an indefinite number of points in the lines thus produced beyond the centre and arcs of circles be described about every one of these as centres, through the said point of contact on one and the same side of the said line produced and each equal in length to the quadrant arc of the given circle reckoning from the aforesaid point of contact to points in the circular arcs, now described, that the locus of these points in the arcs will be a circle, and moreover that the centre thereof will be in the said tangent.'

In order to determine the truth or fallacy of this I will premise the following Lemma.

LEMMA. Let PA be the aforesaid tangent, A the aforesaid point of contact, AH , AE the two lines passing through A and cutting the locus in H and E , the $\angle EAP$ being double HAP , or which is the same thing $HAE = HAP$, also let AhH , AeE be arcs of circles of equal length (and equal to the quadrant arc of the given circle) passing through H , A , and E , A whose centres are on the same side of AP and in the line perpendicular thereto at A ; join H , E and make HL perpendicular to AP ; then I say HE is equal to HL and angle HEL a right angle.

For from the point B, the intersection of AeE and AH , draw BD and BR perpendicular to AP and AE , and join B, E ; now since the centres of AH and AeB are in the line perpendicular to AP at A , AP is a tangent to both, consequently the angle HAL , the angle of chord and tangent of both arcs, being the same

same the arcs are similar. Furthermore the angle AEB in the alternate segment is equal to the angle BAD , which by hypothesis is equal the angle BAE , therefore $BAE = BEA$, therefore $AR = AD = RE$, consequently $\angle AD = AE$, and AeE , that is by hypothesis, $AhH = \angle AeB$, therefore is $AH = \angle AB$, or by similar \triangle s $AL = \angle AD$, equal from above to AE ; hence the triangles AHL and AHE having AH common, the angles at A equal, and the side AL in the one equal to AE in the other, are equal in every respect; therefore $HE = HL$ and $\angle HEA$ equal the right $\angle ALH$. Q. E. D.

COROLLARY. The tangent to the locus at its intersection with AP is perpendicular to AP , and consequently if the figure were a circle the centre would be in the line AP and therefore the latter part of the assertion would be true; for produce HE both ways to C and to Q , its intersection with AP , then the $\angle CQA$ is equal a right angle less the angle EAQ , but it is evident if H and E were to coincide CQ would be a tangent to the coincident points H and E , and then the angle EAH vanishing, EAQ its double must also vanish, and therefore E , H , Q coincide with the intersection of the locus and AP ; also Q a right angle and CH a tangent to the locus at the said intersection.

Q. E. D.

Hence the locus cannot be a circle. For draw the right line AN making the angle NAP equal to $\angle EAP$ cutting the locus in N ; join EN , bisect HE and EN in S and G ; draw SF perpendicular to HE ; join H , E , and G with F , and draw ME perpendicular and AP parallel to AP and suppose the locus a circle then its centre must be in the line SF bisecting the chord at right angles, but by the Corollary to the Lemma it is in AP , therefore F is the centre; consequently the angle G of a line from the centre bisecting a chord a right angle, but by the Lemma ANE and AEH are right angles, therefore FS and FG parallel to AE and AN respectively; but by construction, the angle NAP is double the angle EAP consequently, substituting equals for equals, the angle GFP is double the angle SFP or the angle GFS equal to SFP , but SFE is equal to HFS , consequently taking equals from equals, the angles EFG and HFP are equal, consequently the triangles EFG and HFL having the angles at F equal, the angles at L and G equal, being both right angles, and the sides HF and EF , being the radii of the same circle, equal; they are equal in every respect, and consequently HL and EG equal, consequently $\angle EG$ or EN and $\angle HL$ or HL more MV are equal, but by the Lemma EN is equal to EM or VE more MV , and HL equal to HE , consequently VE and MV is equal to HE and MV , and

and

and consequently VE and HE are equal, that is, the hypotenuse of a right angled triangle equal to one of the other sides which is absurd.

Q. E. D.

Note. Let y denote the radius of the given circle, q the length of a quadrant in the circle having unity for radius, and x the radius of one of the circles touching the given line at the given point of contact; then $\frac{y}{x} \times q$ will denote the measure of the arch intercepted between the point of contact and the locus; and the length of the chord of the arch will be $2x \times \sin \frac{y}{2x} \times q$.

But the angle made by the chord with the given tangent will be half the angle at the centre standing upon the arch; that is it will be measured by $\frac{y}{2x} \times q$. Hence if we conceive the locus to be generated by the gyration of a straight line about the given point of contact as a pole, and call ρ the revolving radius and ϕ the measure of the angle made by it with the given tangent, we shall have

$$\rho = 2x \times \sin \frac{y}{2x} \times q$$

$$\rho = \frac{y}{2x} \times q.$$

And exterminating x , the equation of the curve is

$$\rho = y \times \frac{q}{\phi} \sin \phi.$$

It may be remarked that by taking x very great, or ϕ very small, the curve approaches to a circle of which $y \times q$ is the radius, and the point of contact the centre, and that it ultimately coincides with this circle when x is infinite.
